ARM1156T2F-S Technical Reference Manual

Preface

About this manual	xxiv
Feedback	xxx

Chapter 1

Introduction

1.1	About the ARM1156T2F-S processor	1-2
1.2	ARM1156T2F-S architecture with Thumb-2 core technology	1-3
1.3	Components of the processor	1-5
1.4	Power management	1-20
1.5	Configurable options	1-22
1.6	Pipeline stages	1-23
1.7	Typical pipeline operations	1-25
1.8	About the architecture	1-31
1.9	Product revisions	1-32

Chapter 2

Programmer's Model

2.1	About the programmer's model	2-2
2.2	Processor operating states	2-3
2.3	Operating modes	2-4
2.4	Data types	2-5
2.5	Memory formats	2-6
2.6	Registers	2-8

2.7	The program status registers	2-12
2.8	Exceptions	2-20
2.9	Acceleration of execution environments	2-40
Chapter 3	System Control Coprocessor	
3.1	About control coprocessor CP15	3-2
3.2	System control processor registers	3-11
3.3	System control coprocessor reference data	3-109
Chapter 4	Prefetch Unit	
4.1	About the prefetch unit	4-2
4.2	Branch prediction	4-3
4.3	Return stack	4-6
4.4	Instruction Memory Barrier (IMB) instruction	4-7
Chapter 5	Memory Protection Unit	
5.1	About the MPU	5-2
5.2	Enabling and disabling the MPU	5-7
5.3	Memory attributes and types	5-10
5.4	Memory region attributes	5-19
5.5	Memory access control	5-22
5.6	MPU aborts	5-23
5.7	Fault status and address	5-25
5.8	MPU fault checking	5-27
5.9	Debug event	5-30
Chapter 6	Unaligned and Mixed-Endian Data Access Support	
6.1	About unaligned and mixed-endian support	6-2
6.2	Unaligned access support	6-3
6.3	Unaligned data access specification	6-7
6.4	Operation of unaligned accesses	6-18
6.5	Mixed-endian access support	6-22
6.6	Instructions to reverse bytes in a general-purpose register	6-29
6.7	Instructions to change the CPSR E bit	6-30
Chapter 7	Level One Memory System	
7.1	About the level one memory system	7-2
7.2	Cache organization	7-3
7.3	Tightly-coupled memory	7-12
7.4	TCM and cache interactions	7-20
7.5	Peripheral port	7-24
7.6	Cache debug	7-25
7.7	Write Buffer	7-26
Chapter 8	Level Two Interface	
8.1	About the level two interface	8-2

8.2	Synchronization primitives	8-6
8.3	AXI control signals in the processor	8-8
8.4	Instruction fetch interface transfers	8-16
8.5	Data read/write interface transfers	8-18
8.6	Peripheral interface transfers	8-45
8.7	Endianness	8-47
8.8	Locked access	8-49
Chapter 9	Clocking and Resets	
9.1	ARM1156T2F-S clocking	9-2
9.2	Reset	9-3
9.3	Reset modes	9-4
Chapter 10	Power Control	
10.1	About power control	10-2
10.2	Power management	10-3
Chapter 11	Coprocessor Interface	
11.1	About the coprocessor interface	11-2
11.2	Coprocessor pipeline	11-3
11.3	Token queue management	11-10
11.4	Token queues	11-14
11.5	Data transfer	11-18
11.6	Operations	11-23
11.7	Multiple coprocessors	11-26
Chapter 12	Vectored Interrupt Controller Port	
12.1	About the PL192 Vectored Interrupt Controller	12-2
12.2	About the ARM1156T2F-S VIC port	12-3
12.3	Timing of the VIC port	12-6
12.4	Interrupt entry flowchart	12-9
Chapter 13	Debug	
13.1	Debug systems	13-2
13.2	About the debug unit	13-4
13.3	Debug registers	13-6
13.4	CP14 registers reset	13-24
13.5	CP14 debug instructions	13-25
13.6	Debug events	13-28
13.7	Debug exception	13-33
13.8	Debug state	13-35
13.9	Debug communications channel	13-39
13.10	Debugging in a cached system	13-40
13.11	Monitor debug-mode debugging	13-41
13.12	Halting debug-mode debugging	13-47
13.13	External signals	13-49

Chapter 14	Debug Test Access Port	
14.1	Debug Test Access Port and Halting debug-mode	14-2
14.2	Synchronizing RealView™ ICE	14-3
14.3	Entering Debug state	14-4
14.4	Exiting Debug state	14-5
14.5	The DBGTAP port and debug registers	14-6
14.6	Debug registers	14-8
14.7	Using the Debug Test Access Port	14-24
14.8	Debug sequences	14-34
14.9	Programming debug events	14-48
14.10	Monitor debug-mode debugging	14-50
Chapter 15	Trace Interface Port	
15.1	About the ETM interface	15-2
Chapter 16	Test Features	
16.1	About the test features	16-2
16.2	Memory BIST	16-3
16.3	Power-On Test	16-12
16.4	Running System Test	16-13
Chapter 17	Cycle Timings and Interlock Behavior	
17.1	About cycle timings and interlock behavior	17-3
17.2	Register interlock examples	17-8
17.3	Data processing instructions	17-9
17.4	QADD, QDADD, QSUB, and QDSUB instructions	17-12
17.5	ARMv6 media data-processing	17-13
17.6	ARMv6 Sum of Absolute Differences	17-15
17.7	Multiplies	17-16
17.8	Branches	17-18
17.9	Processor state updating instructions	17-19
17.10	Single load and store instructions	17-20
17.11	Load and Store Doubleword instructions	17-23
17.12	Load and Store Multiple instructions	17-25
17.13	RFE and SRS instructions	17-28
17.14	Synchronization instructions	17-29
17.15	Coprocessor instructions	17-30
17.16	SVC, BKPT, undefined, and prefetch aborted instructions	17-31
17.17	CBZ, CBNZ, and IT instructions	17-32
17.18	Bitfield instructions	17-33
17.19	NOP (CPS) instruction	17-34
17.20	Table branch instructions	17-35
Chapter 18	AC Characteristics	
18.1	ARM1156T2F-S timing diagrams	18-2
18.2	ARM1156T2F-S timing parameters	18-3

Chapter 19	VFP Introduction	
19.1	About the VFP11 coprocessor	19-2
19.2	Applications	19-3
19.3	Coprocessor interface	19-4
19.4	VFP11 coprocessor pipelines	19-5
19.5	Modes of operation	19-12
19.6	Short vector instructions	19-15
19.7	Parallel execution of instructions	19-16
19.8	VFP11 treatment of branch instructions	19-17
19.9	Writing optimal VFP11 code	19-18
19.10	VFP11 revision information	19-19
 Chapter 20	 VFP Register File	
20.1	About the register file	20-2
20.2	Register file internal formats	20-3
20.3	Decoding the register file	20-5
20.4	Loading operands from ARM11 registers	20-6
20.5	Maintaining consistency in register precision	20-8
20.6	Data transfer between memory and VFP11 registers	20-9
20.7	Access to register banks in CDP operations	20-11
 Chapter 21	 VFP Programmer's Model	
21.1	About the programmer's model	21-2
21.2	Compliance with the IEEE 754 standard	21-3
21.3	ARMv5TE coprocessor extensions	21-10
21.4	VFP11 system registers	21-16
 Chapter 22	 VFP Instruction Execution	
22.1	About instruction execution	22-2
22.2	Serializing instructions	22-3
22.3	Interrupting the VFP11 coprocessor	22-4
22.4	Forwarding	22-5
22.5	Hazards	22-7
22.6	Operation of the scoreboards	22-8
22.7	Data hazards in full-compliance mode	22-15
22.8	Data hazards in RunFast mode	22-19
22.9	Resource hazards	22-20
22.10	Parallel execution	22-23
22.11	Execution timing	22-25
 Chapter 23	 VFP Exception Handling	
23.1	About exception processing	23-2
23.2	Bounced instructions	23-3
23.3	Support code	23-5
23.4	Exception processing	23-8
23.5	Input Subnormal exception	23-14

23.6 Invalid Operation exception 23-15

23.7 Division by Zero exception 23-18

23.8 Overflow exception 23-19

23.9 Underflow exception 23-21

23.10 Inexact exception 23-23

23.11 Input exceptions 23-24

23.12 Arithmetic exceptions 23-25

Appendix A Processor Signal Descriptions

A.1 Global signals A-2

A.2 Configuration signals A-3

A.3 Interrupt signals (including VIC interface signals) A-4

A.4 AXI interface signals A-5

A.5 Instruction TCM Interface A-10

A.6 Data TCM Interface A-11

A.7 Coprocessor interface signals A-12

A.8 Debug interface signals (including JTAG) A-14

A.9 ETM interface signals A-15

A.10 Test signals A-16

Glossary

List of Tables

ARM1156T2F-S Technical Reference Manual

	Change history	ii
Table 1-1	Flush-to-zero mode	1-17
Table 1-2	Configurable options	1-22
Table 2-1	Register mode identifiers	2-9
Table 2-2	Shifting of IT execution state bits	2-14
Table 2-3	Effect of IT execution state bits	2-14
Table 2-4	GE[3:0] settings	2-16
Table 2-5	PSR mode bit values	2-18
Table 2-6	Exception entry and exit	2-22
Table 2-7	Configuration of exception vector address locations	2-38
Table 2-8	Exception vectors	2-38
Table 2-9	Jazelle register instruction summary	2-40
Table 3-1	CP15 register functions	3-3
Table 3-2	Register allocation	3-14
Table 3-3	MCRR operations	3-18
Table 3-4	Main ID Register bit functions	3-19
Table 3-5	Cache Type Register bit functions	3-20
Table 3-6	Instruction and data cache sizes	3-21
Table 3-7	Instruction and data cache associativity	3-22
Table 3-8	Cache Type Register default values	3-22
Table 3-9	Cache Type Register values for zero cache size	3-23
Table 3-10	TCM Status Register bit functions	3-24
Table 3-11	MPU Type Register bit functions	3-26

Table 3-12	Processor Feature Register 0 bit functions	3-27
Table 3-13	Processor Feature Register 1 bit functions	3-29
Table 3-14	Debug Feature Register 0 bit functions	3-30
Table 3-15	Memory Model Feature Register 0 bit functions	3-32
Table 3-16	Memory Model Feature Register 1 bit functions	3-33
Table 3-17	Memory Model Feature Register 2 bit functions	3-35
Table 3-18	Memory Model Feature Register 3 bit functions	3-37
Table 3-19	Instruction Set Attributes Register 0 bit functions	3-38
Table 3-20	Instruction Set Attributes Register 1 bit functions	3-39
Table 3-21	Instruction Set Attributes Register 2 bit functions	3-41
Table 3-22	Instruction Set Attributes Register 3 bit functions	3-43
Table 3-23	Instruction Set Attributes Register 4 bit functions	3-45
Table 3-24	Control Register bit functions	3-47
Table 3-25	Resultant B bit, U bit, and EE bit values	3-49
Table 3-26	Auxiliary Control Register bit functions	3-51
Table 3-27	Coprocessor Access Control Register bit functions	3-53
Table 3-28	DFSR bit functions	3-55
Table 3-29	IFSR bit functions	3-56
Table 3-30	Region Base Address Register bit functions	3-60
Table 3-31	Region Size Register bit functions	3-62
Table 3-32	Region Access Control Register bit functions	3-63
Table 3-33	Access data permission bit encoding	3-64
Table 3-34	Memory Region Number Register bit functions	3-65
Table 3-35	Cache Operations Register bit functions for Way and Set	3-69
Table 3-36	Cache size and Way associativity	3-69
Table 3-37	Cache size and S parameter dependency	3-70
Table 3-38	Cache Operations Register bit functions for address	3-71
Table 3-39	Cache Operations Register functions for single lines	3-72
Table 3-40	Cache Operations Register functions for entire cache	3-73
Table 3-41	Cache Operations Register Flush functions	3-74
Table 3-42	Exception behavior to range operations	3-75
Table 3-43	Cache Operations Register functions for address ranges	3-75
Table 3-44	Results of access to the Data Memory Barrier operation	3-76
Table 3-45	Instruction and Data Cache Lockdown Registers bit functions	3-80
Table 3-46	Data TCM Region Register bit functions	3-82
Table 3-47	Instruction TCM region register bit functions	3-84
Table 3-48	Data Cache Debug Register bit arrangement after a Data Tag RAM read/write operation	3-87
Table 3-49	Data Cache Debug Register bit arrangement after a Data Tag RAM parity read operation	3-87
Table 3-50	Data Cache Debug Register bit arrangement after a Data Cache Data RAM parity read operation	3-87
Table 3-51	Data Cache Debug Register bit arrangement after a Data Valid and Dirty RAM write operation	3-88
Table 3-52	Instruction Cache Debug Register bit arrangement after an Instruction cache Tag RAM read/write operation	3-89

Table 3-53	Instruction Cache Debug Register bit arrangement after an Instruction cache Tag RAM parity read operation	3-89
Table 3-54	Instruction Cache Debug Register bit arrangement after an Instruction Cache Data RAM parity read operation	3-90
Table 3-55	Data Tag RAM read/write operation bit functions	3-91
Table 3-56	Data Tag RAM parity read operation bit functions	3-92
Table 3-57	Instruction cache Tag RAM read/write operation bit functions	3-93
Table 3-58	Instruction Cache Data RAM read/write operation bit functions	3-95
Table 3-59	Cache Data RAM parity read operation bit functions	3-96
Table 3-60	Cache Debug Control Register bit functions	3-99
Table 3-61	Data Cache Valid RAM and Dirty RAM bit write operation bit functions	3-100
Table 3-62	Performance Monitor Control Register bit functions	3-101
Table 3-63	Performance monitoring events	3-103
Table 3-64	Summary of CP15 instructions	3-109
Table 5-1	Memory attributes	5-10
Table 5-2	Memory ordering restrictions	5-15
Table 5-3	Memory region backwards compatibility	5-18
Table 5-4	TEX field, and C and B bit encodings used in Region Access Control Registers ...	5-19
Table 5-5	Cache policy bits	5-20
Table 5-6	Inner and Outer cache policy implementation options	5-21
Table 5-7	Access data permission bit encoding	5-22
Table 5-8	Encodings for the fault status registers	5-25
Table 5-9	Summary of aborts	5-25
Table 6-1	Unaligned access handling	6-4
Table 6-2	Access type descriptions	6-18
Table 6-3	Alignment fault occurrence when access behavior is architecturally unpredictable	6-19
Table 6-4	Byte lanes used for LE, BE-8 and BE-32 accesses	6-23
Table 6-5	Effect on E and B bits on instruction and data endianness	6-24
Table 6-6	Word-invariant endianness using CP15 c1	6-25
Table 6-7	Mixed-endian configuration	6-27
Table 6-8	B bit, U bit, and EE bit settings	6-28
Table 7-1	Effect of cache parity errors	7-10
Table 7-2	Summary of data accesses to TCM and caches	7-22
Table 7-3	Summary of instruction accesses to TCM and caches	7-23
Table 8-1	AXI parameters for the level 2 interconnect interfaces	8-3
Table 8-2	AxLEN[3:0] encoding	8-11
Table 8-3	AxSIZE[2:0] encoding	8-12
Table 8-4	AxBURST[1:0] encoding	8-12
Table 8-5	AxLOCK[1:0] encoding	8-13
Table 8-6	AxCACHE[3:0] encoding	8-13
Table 8-7	AxPROT[2:0] encoding	8-14
Table 8-8	AxSIDE BAND[4:1] encoding	8-14
Table 8-9	AR SIDE BAND I[4:1] encoding	8-15
Table 8-10	AXI signals for Cacheable fetches	8-16
Table 8-11	AXI signals for Noncacheable fetches	8-17
Table 8-12	Linefill behavior on the AXI interface	8-19
Table 8-13	Noncacheable LDRB	8-19

Table 8-14	Noncacheable LDRH	8-20
Table 8-15	Noncacheable LDR or LDM1	8-20
Table 8-16	Noncacheable LDRD or LDM2	8-21
Table 8-17	Noncacheable LDRD or LDM2 from word 7	8-22
Table 8-18	Noncacheable LDM3, Strongly Ordered or Device memory	8-22
Table 8-19	Noncacheable LDM3, Noncacheable memory or cache disabled	8-22
Table 8-20	Noncacheable LDM3 from word 6, or 7	8-23
Table 8-21	Noncacheable LDM4, Strongly Ordered or Device memory	8-23
Table 8-22	Noncacheable LDM4, Noncacheable memory or cache disabled	8-23
Table 8-23	Noncacheable LDM4 from word 5, 6, or 7	8-24
Table 8-24	Noncacheable LDM5, Strongly Ordered or Device memory	8-24
Table 8-25	Noncacheable LDM5, Noncacheable memory or cache disabled	8-24
Table 8-26	Noncacheable LDM5 from word 4, 5, 6, or 7	8-25
Table 8-27	Noncacheable LDM6, Strongly Ordered or Device memory	8-25
Table 8-28	Noncacheable LDM6, Noncacheable memory or cache disabled	8-25
Table 8-29	Noncacheable LDM6 from word 3, 4, 5, 6, or 7	8-26
Table 8-30	Noncacheable LDM7, Strongly Ordered or Device memory	8-26
Table 8-31	Noncacheable LDM7, Noncacheable memory or cache disabled	8-26
Table 8-32	Noncacheable LDM7 from word 2, 3, 4, 5, 6, or 7	8-27
Table 8-33	Noncacheable LDM8 from word 0	8-27
Table 8-34	Noncacheable LDM8 from word 1, 2, 3, 4, 5, 6, or 7	8-27
Table 8-35	Noncacheable LDM9	8-28
Table 8-36	Noncacheable LDM10	8-28
Table 8-37	Noncacheable LDM11	8-29
Table 8-38	Noncacheable LDM12	8-29
Table 8-39	Noncacheable LDM13	8-30
Table 8-40	Noncacheable LDM14	8-30
Table 8-41	Noncacheable LDM15	8-31
Table 8-42	Noncacheable LDM16	8-31
Table 8-43	Half-line Write-Back	8-32
Table 8-44	Full-line Write-Back	8-33
Table 8-45	Cacheable Write-Through or Noncacheable STRB	8-33
Table 8-46	Cacheable Write-Through or Noncacheable STRH	8-34
Table 8-47	Cacheable Write-Through or Noncacheable STR or STM1	8-34
Table 8-48	Cacheable Write-Through or Noncacheable STRD or STM2 to words 0 to 6	8-35
Table 8-49	Cacheable Write-Through or Noncacheable STRD or STM2 to word 7	8-36
Table 8-50	Cacheable Write-Through or Noncacheable STM3 to words 0, 1, 2, 3, 4, or 5	8-36
Table 8-51	Cacheable Write-Through or Noncacheable STM3 to words 6 or 7	8-36
Table 8-52	Cacheable Write-Through or Noncacheable STM4 to word 0, 1, 2, 3, or 4	8-37
Table 8-53	Cacheable Write-Through or Noncacheable STM4 to word 5, 6, or 7	8-37
Table 8-54	Cacheable Write-Through or Noncacheable STM5 to word 0, 1, 2, or 3	8-37
Table 8-55	Cacheable Write-Through or Noncacheable STM5 to word 4, 5, 6, or 7	8-38
Table 8-56	Cacheable Write-Through or Noncacheable STM6 to word 0, 1, or 2	8-38
Table 8-57	Cacheable Write-Through or Noncacheable STM6 to word 3, 4, 5, 6, or 7	8-38
Table 8-58	Cacheable Write-Through or Noncacheable STM7 to word 0 or 1	8-39
Table 8-59	Cacheable Write-Through or Noncacheable STM7 to words 2 to 7	8-39
Table 8-60	Cacheable Write-Through or Noncacheable STM8 to word 0	8-39

Table 8-61	Cacheable Write-Through or Noncacheable STM8 to words 1 to 7	8-40
Table 8-62	Cacheable Write-Through or Noncacheable STM9	8-40
Table 8-63	Cacheable Write-Through or Noncacheable STM10	8-41
Table 8-64	Cacheable Write-Through or Noncacheable STM11	8-41
Table 8-65	Cacheable Write-Through or Noncacheable STM12	8-42
Table 8-66	Cacheable Write-Through or Noncacheable STM13	8-42
Table 8-67	Cacheable Write-Through or Noncacheable STM14	8-43
Table 8-68	Cacheable Write-Through or Noncacheable STM15	8-43
Table 8-69	Cacheable Write-Through or Noncacheable STM16	8-44
Table 8-70	Example Peripheral interface reads and writes	8-45
Table 8-71	Endianness configuration	8-47
Table 9-1	Reset modes	9-4
Table 11-1	Coprocessor instructions	11-3
Table 11-2	Coprocessor control signals	11-4
Table 11-3	Pipeline stage update	11-8
Table 11-4	Addressing of queue buffers	11-11
Table 11-5	Retirement conditions	11-25
Table 12-1	VIC port signals	12-3
Table 13-1	Terms used in register descriptions	13-6
Table 13-2	CP14 debug register map	13-7
Table 13-3	Debug ID Register bitfield definition	13-8

Preface

This preface introduces the *ARM1156T2F-S[™] r0p4 Technical Reference Manual* (TRM). It contains the following sections:

- *About this manual* on page xxiv
- *Feedback* on page xxxi.

About this manual

This is the technical reference manual for the ARM1156T2F-S™ processor. In this manual the generic term processor means the ARM1156T2F-S processor.

Product revision status

The *mpn* identifier indicates the revision status of the product described in this manual, where:

rn Identifies the major revision of the product.

pn Identifies the minor revision or modification status of the product.

Intended audience

This manual has been written for hardware and software engineers implementing processor system designs. It provides information to enable designers to integrate the processor into a target system as quickly as possible.

Using this manual

This manual is organized into the following chapters:

Chapter 1 *Introduction*

Read this chapter for an introduction to the processor and descriptions of the major functional blocks.

Chapter 2 *Programmer's Model*

Read this chapter for a description of the ARM1156T2F-S registers and programming details.

Chapter 3 *System Control Coprocessor*

Read this chapter for a description of the ARM1156T2F-S control coprocessor CP15 registers and programming details.

Chapter 4 *Prefetch Unit*

Read this chapter for a description of the functions of the ARM1156T2F-S Prefetch Unit, including branch prediction and the return stack.

Chapter 5 *Memory Protection Unit*

Read this chapter for a description of the ARM1156T2F-S *Memory Protection Unit* (MPU) and the access permissions process.

Chapter 6 *Unaligned and Mixed-Endian Data Access Support*

Read this chapter for a description of the processor support for unaligned and mixed-endian data accesses.

Chapter 7 *Level One Memory System*

Read this chapter for a description of the ARM1156T2F-S level one memory system, including caches, *Tightly-Coupled Memory* (TCM) and write buffer.

Chapter 8 *Level Two Interface*

Read this chapter for a description of the ARM1156T2F-S level two memory interface and the peripheral port.

Chapter 9 *Clocking and Resets*

Read this chapter for a description of the ARM1156T2F-S clocking modes and the reset signals.

Chapter 10 *Power Control*

Read this chapter for a description of the ARM1156T2F-S power control facilities.

Chapter 11 *Coprocessor Interface*

Read this chapter for details of the ARM1156T2F-S coprocessor interface.

Chapter 12 *Vectored Interrupt Controller Port*

Read this chapter for a description of the ARM1156T2F-S *Vectored Interrupt Controller* (VIC) interface.

Chapter 13 *Debug*

Read this chapter for a description of the ARM1156T2F-S debug support.

Chapter 14 *Debug Test Access Port*

Read this chapter for a description of the JTAG-based ARM1156T2F-S Debug Test Access Port.

Chapter 15 *Trace Interface Port*

Read this chapter for a description of the *Embedded Trace Macrocell* (ETM) interface port.

Chapter 16 *Test Features*

Read this chapter for a description of the ARM1156T2F-S test features.

Chapter 17 *Cycle Timings and Interlock Behavior*

Read this chapter for a description of the ARM1156T2F-S instruction cycle timing and for details of instruction interlocks.

Chapter 18 *AC Characteristics*

Read this chapter for a description of the timing parameters applicable to the processor.

Chapter 19 *VFP Introduction*

Read this chapter for an introduction to the VFP11 coprocessor.

Chapter 20 *VFP Register File*

Read this chapter for a description of the structure and operation of the VFP11 register file.

Chapter 21 *VFP Programmer's Model*

Read this chapter for a description of the VFPv2 architecture compliance with the IEEE 754 standard, the VFP11 status and control registers, and the VFP11 coprocessor extensions.

Chapter 22 *VFP Instruction Execution*

Read this chapter for details about the forwarding, hazards, and parallel execution in the VFP11 instruction pipelines.

Chapter 23 *VFP Exception Handling*

Read this chapter for a description of the VFP11 exceptional conditions and how they are handled in hardware and software.

Appendix A *Processor Signal Descriptions*

Read this appendix for a description of the inputs and outputs of the processor.

Conventions

Conventions that this manual can use are described in:

- *Typographical*
- *Timing diagrams*
- *Signal naming* on page xxviii
- *Numbering* on page xxix.

Typographical

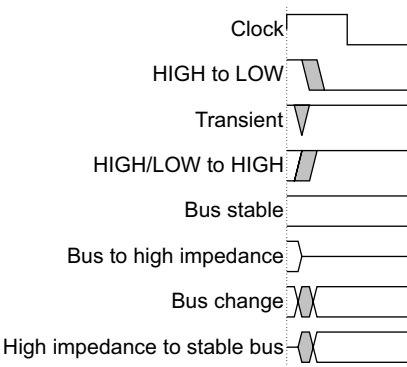

The typographical conventions are:

<i>italic</i>	Highlights important notes, introduces special terminology, denotes internal cross-references, and citations.
bold	Highlights interface elements, such as menu names. Denotes ARM processor signal names. Also used for terms in descriptive lists, where appropriate.
<code>monospace</code>	Denotes text that you can enter at the keyboard, such as commands, file and program names, and source code.
<u><code>monospace</code></u>	Denotes a permitted abbreviation for a command or option. You can enter the underlined text instead of the full command or option name.
<i>monospace italic</i>	Denotes arguments to monospace text where the argument is to be replaced by a specific value.
monospace bold	Denotes language keywords when used outside example code.
< and >	Angle brackets enclose replaceable terms for assembler syntax where they appear in code or code fragments. They appear in normal font in running text. For example: <ul style="list-style-type: none"> • MRC p15, 0 <Rd>, <CRn>, <CRm>, <Opcode_2> • The Opcode_2 value selects which register is accessed.

Timing diagrams

The figure named *Key to timing diagram conventions* on page xxviii explains the components used in timing diagrams. Variations, when they occur, have clear labels. You must not assume any timing information that is not explicit in the diagrams.

Shaded bus and signal areas are undefined, so the bus or signal can assume any value within the shaded area at that time. The actual level is unimportant and does not affect normal operation.

Key to timing diagram conventions

Signal naming

The level of an asserted signal depends on whether the signal is active-HIGH or active-LOW. Asserted means HIGH for active-HIGH signals and LOW for active-LOW signals:

- Prefix A** Denotes *Advanced eXtensible Interface* (AXI) global and address channel signals.
- Prefix ACP, CPA** Denotes coprocessor interface signals.
- Prefix B** Denotes AXI write response channel signals.
- Prefix C** Denotes AXI low-power interface signals.
- Prefix n** Denotes active-LOW signals except in the case of *Advanced High-performance Bus* (AHB) or *Advanced Peripheral Bus* (APB) reset signals. These are named **HRESETn** and **PRESETn** respectively.
- Prefix R** Denotes AXI read channel signals.
- Prefix W** Denotes AXI write channel signals.

Numbering

The Verilog numbering convention is:

<size in bits>'<base><number>

This is a Verilog method of abbreviating constant numbers. For example:

- 'h7B4 is an unsized hexadecimal value.
- 'o7654 is an unsized octal value.
- 8'd9 is an eight-bit wide decimal value of 9.
- 8'h3F is an eight-bit wide hexadecimal value of 0x3F. This is equivalent to b00111111.
- 8'b1111 is an eight-bit wide binary value of b00001111.

Further reading

This section lists publications by ARM Limited, and by third parties.

ARM periodically provides updates and corrections to its documentation. See <http://www.arm.com> for current errata sheets, addenda, and the ARM Frequently Asked Questions list.

ARM publications

This manual contains information that is specific to the ARM1156T2F-S processor. Refer to the following documents for other relevant information:

Feedback

ARM Limited welcomes feedback on the ARM1156T2F-S processor, and the documentation.

Feedback on the product

If you have any comments or suggestions about this product, contact your supplier giving:

- the product name
- a concise explanation of your comments.

Feedback on this manual

If you have any comments about this manual, send e-mail to errata@arm.com giving:

- the document title
- the document number
- the page number(s) to which your comments refer
- a concise explanation of your comments.

ARM Limited also welcomes general suggestions for additions and improvements.

Chapter 1

Introduction

This chapter introduces the ARM1156T2F-S processors and their features. It contains the following sections:

- *About the ARM1156T2F-S processor* on page 1-2
- *ARM1156T2F-S architecture with Thumb-2 core technology* on page 1-3
- *Components of the processor* on page 1-5
- *Power management* on page 1-20
- *Configurable options* on page 1-22
- *Pipeline stages* on page 1-23
- *Typical pipeline operations* on page 1-25
- *About the architecture* on page 1-31
- *Product revisions* on page 1-32.

1.1 About the ARM1156T2F-S processor

The ARM1156T2F-S processor incorporates an integer unit that implements the ARM architecture v6. It supports the ARM and Thumb 2 instruction sets, and a range of *Single Instruction, Multiple-Data* (SIMD) DSP instructions that operate on 16-bit or 8-bit data values in 32-bit registers.

The ARM1156T2F-S processor features:

- Thumb-2 core technology
- an integer unit with integral EmbeddedICE-RT logic
- a high-speed *Advanced Microprocessor Bus Architecture* (AMBA) *Advanced eXtensible Interface* (AXI) for level two interfaces supporting prioritized multiprocessor implementations
- a nine-stage pipeline
- branch prediction with return stack
- low interrupt latency
- external coprocessor interface and coprocessors CP14 and CP15
- optional Instruction and Data *Memory Protection Units* (MPUs)
- optional Instruction and data caches, including a non-blocking data cache with *Hit-Under-Miss* (HUM)
- 64-bit interface to both caches
- a bypassable write buffer
- level one *Tightly-Coupled Memory* (TCM) that can be used as a local RAM
- *Vector Floating-Point* (VFP) coprocessor
- trace support
- JTAG-based debug.

———— **Note** ————

The only difference between the ARM1156T2-S processor and the ARM1156T2F-S processor is that the ARM1156T2F-S processor includes a *Vector Floating-Point* (VFP) coprocessor.

1.2 ARM1156T2F-S architecture with Thumb-2 core technology

The ARM1156T2F-S processor supports:

- the 32-bit ARM instruction set used in ARM state
- the 16-bit and 32-bit Thumb-2 instruction set used in Thumb state.

1.2.1 The Thumb-2 instruction set

Thumb-2 is a superset of the Thumb instruction set. Thumb-2 introduces 32-bit instructions that are intermixed with the 16-bit instructions. The Thumb-2 instruction set covers almost all the functionality of the ARM instruction set. Thumb-2 is backwards compatible with the ARMv6 Thumb instruction set. Any code that you have compiled to run on the ARMv6 thumb instruction set runs on the Thumb-2 instruction set.

The most important difference between the Thumb-2 instruction set and the ARM instruction set is that most Thumb-2 instructions are unconditional, where as almost all ARM instructions can be conditional. However, Thumb-2 introduces a new conditional execution instruction, IT, that is a logical if-then-else function.

Thumb-2 has the performance close to or better than that of the ARM instruction set and has the code density of the original Thumb ISA.

In addition to the new 32-bit Thumb instructions, there are several new 16-bit Thumb instructions. Several new 32-bit ARM instructions are introduced at the same time.

The main enhancements are:

- 32-bit instructions added to the Thumb instruction set to:
 - provide support for exception handling in Thumb state
 - provide access to coprocessors
 - include DSP and media instructions
 - improve performance in cases where a single 16-bit instruction restricts functions available to the compiler.
- Addition of a 16-bit IT instruction that enables 1 - 4 following Thumb instructions to be conditional.
- Addition of 16-bit *Compare and Branch on Zero* (CBZ) and *Compare and Branch on Non Zero* (CBNZ) instructions to improve code size by replacing two-instruction sequence with a single instruction.

The 32-bit ARM Thumb-2 instructions are added in the space occupied by the Thumb BL and BLX instructions. The 32-bit ARM Thumb-2 instruction format is shown in Figure 1-1.

Figure 1-1 32-bit ARM Thumb-2 instruction format

The instruction length and functionality is determined by *first halfword* (hw1). If the instruction is decoded as being 32-bits long, the *second halfword* (hw2) of the instruction is fetched from the instruction address plus two.

For details on Thumb-2 operations and assembler, see the *ARM Architecture Reference Manual*.

1.3 Components of the processor

The main components of the ARM1156T2F-S processor are:

- *Core* on page 1-6
- *Load Store Unit (LSU)* on page 1-9
- *PreFetch Unit (PFU)* on page 1-9
- *Level one memory system* on page 1-10
- *AMBA AXI interface* on page 1-12
- *Coprocessor interface* on page 1-14
- *Debug* on page 1-15
- *Vector Floating-Point (VFP)* on page 1-16
- *System control coprocessor* on page 1-17
- *Interrupt handling* on page 1-18.

Figure 1-2 shows the structure of the ARM1156T2F-S processor.

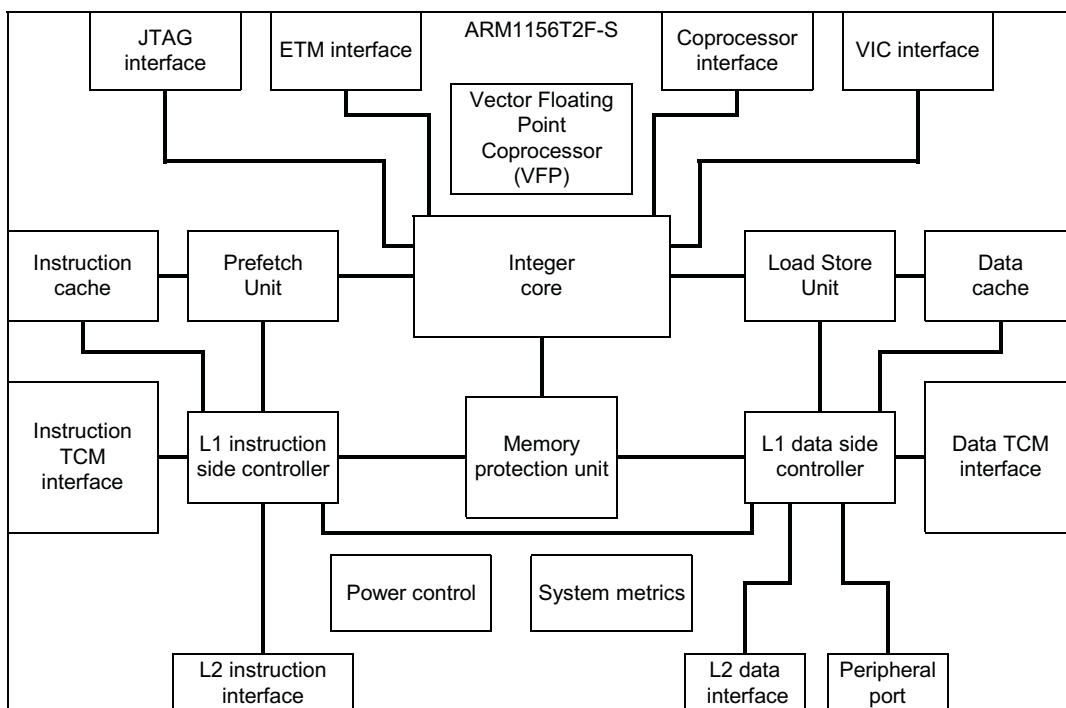

Figure 1-2 ARM1156T2F-S processor block diagram

1.3.1 Core

The ARM1156T2F-S processor is built around the ARM11 core in an ARM architecture v6 implementation that runs the 32-bit ARM and 16-bit and 32-bit Thumb-2 instruction sets. The processor contains EmbeddedICE-RT logic and a JTAG debug interface to enable hardware debuggers to access the processor. The following sections describe the core in more detail:

- *Instruction sets*
- *Conditional execution*
- *Registers* on page 1-7
- *Modes and exceptions* on page 1-7
- *DSP instructions* on page 1-7
- *Media extensions* on page 1-8
- *Instruction cycle summary and interlocks* on page 1-8
- *Datapath* on page 1-8.

Instruction sets

The instruction sets are divided into six categories:

- branch instructions
- data processing instructions
- status register transfer instructions
- load and store instructions
- coprocessor instructions
- exception-generating instructions.

Note

Only load and store instructions can access data from memory.

Conditional execution

The processor conditionally executes all ARM instructions. You can decide if the condition code flags, Negative, Zero, Carry, and Overflow, are updated according to their result. A Thumb-2 instruction, *If-Then* (IT), is added to enable conditional execution. It enables 1 - 4 following Thumb instructions to be conditional, without using 4 bits on every instruction of ARM conditional execution.

Registers

The ARM1156T2F-S core contains:

- 31 general-purpose 32-bit registers
- six dedicated 32-bit registers.

Note

At any one time, 16 registers are visible. The remainder are banked registers used to speed up exception processing.

Modes and exceptions

The core provides a set of operating and exception modes, to support systems combining complex operating systems, user applications, and real-time demands. There are seven operating modes, five of which are exception processing modes:

- User
- System
- fast interrupt
- normal interrupt
- memory aborts
- Supervisor
- Undefined instruction.

DSP instructions

The ARM DSP instruction set extensions provide the following:

- 16-bit data operations
- saturating arithmetic
- MAC operations.

The processor executes multiply instructions using a single-cycle 32x16 implementation. The processor can perform 32x32, 32x16, and 16x16 multiply instructions.

Media extensions

The ARMv6 instruction set provides media instructions to complement the DSP instructions. The media instructions are divided into the following main groups:

- Additional multiplication instructions for handling 16-bit and 32-bit data, including dual-multiplication instructions that operate on both 16-bit halves of their source registers.
- Instructions to perform *Single Instruction Multiple Data* (SIMD) operations on pairs of 16-bit values held in a single register, or on quadruplets of 8-bit values held in a single register. The main operations supplied are addition and subtraction, selection, pack, and saturation.
- Instructions to extract bytes and halfwords from registers and zero-extend or sign-extend them. These include a parallel extraction of two bytes followed by extension of each byte to a halfword.
- Instructions to perform the unsigned *Sum-of-Absolute-Differences* (SAD) operation. This is used in MPEG motion estimation.

Instruction cycle summary and interlocks

Chapter 17 *Cycle Timings and Interlock Behavior* describes instruction cycles and gives examples of interlock timing.

Datapath

The datapath consists of a:

- Shift, ALU and Sat pipe
- MAC pipe
- load-store pipe, see *Load Store Unit (LSU)* on page 1-9.

Shift, ALU, and Sat pipe

The ALU, shift and Sat pipe executes most of the ALU operations, and includes a 32-bit barrel shifter. It consists of three pipeline stages:

Shift	<p>The Shift stage contains the full barrel shifter. All shifts, including those required by the LSU, are performed in this stage.</p> <p>The saturating left shift, which doubles the value of an operand and saturates it, is implemented in the Shift stage.</p>
ALU	<p>The ALU stage performs all arithmetic and logic operations, and generates the condition codes for instructions that set these operations.</p>

The ALU stage consists of a logic unit, an arithmetic unit, and a flag generator. The pipeline logic evaluates the flag settings in parallel with the main adder in the ALU. The flag generator is enabled only on flag-setting operations.

The ALU stage separates the carry chains of the main adder enable 8 and 16-bit SIMD instructions for DSP operations.

Sat The Sat stage implements the saturation logic required by the various classes of DSP instructions.

MAC pipe

The MAC pipeline executes all of the enhanced multiply and multiply-accumulate instructions.

The MAC unit consists of a 32x16 multiplier plus an accumulate unit that is configured to calculate the sum of two 16x16 multiplies. The accumulate unit has its own dedicated single register read port for the accumulate operand.

To minimize power consumption, the processor only clocks each of the MAC and ALU stages when required.

————— Note —————

For details on pipeline stages and instruction progression, see *Pipeline stages* on page 1-23

For details on system coprocessor programming, see Chapter 3 *System Control Coprocessor*

1.3.2 Load Store Unit (LSU)

The *Load Store Unit* (LSU) manages all load and store operations. The load-store pipeline decouples loads and stores from the MAC and ALU pipelines.

When the processor issues load multiple, LDM, and store multiple, STM, instructions to the load-store pipeline, other instructions run concurrently, subject to the requirements of supporting precise exceptions.

1.3.3 PreFetch Unit (PFU)

The *PreFetch Unit* (PFU) obtains instructions from the instruction cache, *Instruction TCM* (ITCM), or from external memory and predicts the outcome of branches in the instruction stream. For more details, see Chapter 4 *Prefetch Unit*.

Branch prediction

The branch predictor is a global type that uses history registers and a 256-entry *Pattern History Table* (PHT).

Return stack

The Prefetch Unit includes a three-entry return stack to accelerate returns from procedure calls. For each procedure call, the return address is pushed onto a hardware stack. When a procedure return is recognized, the address held in the return stack is popped, and is used by the prefetch unit as the predicted return address.

1.3.4 Level one memory system

The processor provides a level one memory system with the following features:

- separate instruction and data caches
- separate instruction and data RAM blocks
- 64-bit datapaths throughout the memory system
- 16 region memory protection unit that supports a wide range of memory sizes
- separate instruction-fetch, data-read/write interfaces, compatible with the AMBA AXI protocol
- 32-bit dedicated peripheral interface
- export of memory attributes for level two memory system.

The level one memory system is described in more detail in the following sections:

- *Instruction and data caches*
- *Cache power management* on page 1-11
- *Memory Protection Unit* on page 1-11
- *Tightly Coupled Memories* on page 1-12
- *Error detection* on page 1-12.

Instruction and data caches

The processor provides separate instruction and data caches. The cache has the following features:

- Independent configuration of the instruction and data cache during synthesis to sizes between 1KB and 64KB.
- Ability to select cache associativity (1KB - 1way, 2KB - 2way, and 4KB and above - 4way). You can lock each way independently.
- Ability to select pseudo-random or round-robin cache replacement policy.

- Eight word cache line length. Cache lines can be either write-back or write-through, determined by MPU entry
- Ability to disable each cache independently.
- Data cache misses that are non-blocking. The processor supports up to three outstanding data cache misses.
- Streaming of sequential data from LDM and LDRD operations, and sequential instruction fetches.
- Critical word first filling of the cache on a cache-miss.
- Implementation of all the cache RAM blocks, and the associated tag and valid RAM blocks using standard ASIC RAM compilers. This ensures optimum area and performance of your designs.

Cache power management

To reduce power consumption, the core uses sequential cache operations to reduce the number of full cache reads. If a cache read is sequential to the previous cache read, and the read is within the same cache line, only the data RAM set that was previously read is accessed. The core does not access Tag RAM during sequential cache operations.

To reduce unnecessary power consumption more, only the addressed words within a cache line are read at any time.

Memory Protection Unit

Because the ARM1156T2F-S processor is targeted at embedded control applications, a small *Memory Protection Unit* (MPU) is used to provide memory attributes. There is an MPU for each of the instruction and data sides of the processor. The MPU has a maximum of 16 regions, each with a minimum resolution of 32 bytes. The regions can overlap with the highest numbered region having the highest priority. For more details, see Chapter 5 *Memory Protection Unit*.

The MPU is responsible for protection checking and memory attributes, some of which can be passed to an external level two memory system.

The MPU has the following features:

- matching of physical address
- checking of access permissions
- checking of memory attributes
- mapping of accesses to cache, TCM, peripheral port, or external memory.

Tightly Coupled Memories

Because some applications might not respond well to caching, configurable memory blocks are provided for Instruction and Data *Tightly Coupled Memories* (TCMs). These ensure high-speed access to code or data.

An *Instruction TCM* (ITCM) is typically used to hold interrupt or exception code that must be accessed at high speed, without any potential delay resulting from a cache miss.

A *Data TCM* (DTCM) is typically used to hold a block of data for intensive processing, such as audio or video processing. You can individually configure the ITCM and DTCM sizes with sizes of 0KB, 4KB, 8KB, 16KB, 32KB, 64KB, 128KB, or 256KB anywhere in the memory map. For flexibility in optimizing the TCM subsystem for performance, power, and RAM type, the TCMs are external to the processor. The **INITRAM** pin enables booting from the ITCM. Both the ITCM and DTCM support wait states. For more details, see Chapter 7 *Level One Memory System*.

Error detection

To increase the tolerance of memory faults you can include parity generation and checking logic for the caches and implement parity generation for the TCMs. For more details, see *Cache parity errors* on page 7-8 and *TCM error detection signals* on page 7-13.

———— Note ————

For TCMs the parity generation and checking logic is external to the processor. This logic is not supplied as part of the core deliverables.

1.3.5 AMBA AXI interface

The bus interface provides high bandwidth between the processor, level two caches, on-chip RAM, peripherals, and interfaces to external memory.

Separate bus interfaces are provided for:

- instruction fetch, 64-bit data
- data read/write, 64-bit data
- peripheral access, 32-bit data.

All buses are multi-layer AXI compatible, enabling them to be merged in smaller systems. The signals on each port provide support to:

- shared-memory synchronization primitives
- level two cache
- bus transactions.

The ports support the following bus transactions:

Instruction fetch

Serves instruction cache misses and noncacheable instruction fetches.

Data read/write

The data read serves data cache misses and noncacheable data reads.

The data write serves cache write-backs (including cache cleans), write-through, and noncacheable data.

Peripheral port

The peripheral port is a 32-bit AXI interface that provides direct access to local, non-shared peripherals without using bandwidth on the main AXI bus system. Accesses to regions of memory that are marked as device and non-shared are routed to the peripheral port instead of to the data read or data write ports.

For more details, see Chapter 8 *Level Two Interface*.

These ports enable several simultaneous outstanding transactions, providing high performance from level two memory systems that support parallelism, and for high utilization of pipelined and multi-page memories such as SDRAM.

The AMBA interface is described in more detail in the following sections:

- *Bus clock*
- *Unaligned accesses*
- *Mixed-endian support* on page 1-14
- *Write buffer* on page 1-14.

Bus clock

The bus interface ports operate synchronously to the CPU clock.

Unaligned accesses

The core supports unaligned data access. Words and halfwords can be aligned to any byte boundary, enabling access to compacted data structures with no software overhead. This is useful for multi-processor applications, pre-ARMv6 code support, and reducing memory space requirements.

The *Bus Interface Unit* (BIU) automatically generates multiple bus cycles for unaligned accesses.

Mixed-endian support

The core provides the option of switching between big and little-endian data access modes. This supports the sharing of data with big-endian systems, and improves handling of certain types of data.

Write buffer

All memory writes take place through the write buffer. The write buffer decouples the CPU pipeline from the system bus for external memory writes. Memory reads are checked for dependency against the write buffer contents.

1.3.6 Coprocessor interface

The ARM1156T2F-S processor controls external coprocessors through the coprocessor interface. This interface supports all ARM coprocessor instructions:

- LDC
- LDCL
- STC
- STCL
- MRC
- MRRC
- MCR
- MCRR
- CDP.

Data for all loads to coprocessors is returned by the memory system in the order of the accesses in the program. HUM operation of the cache is suppressed for coprocessor instructions.

The external coprocessor interface assumes that all coprocessor instructions are executed in order.

Externally-connected coprocessors follow the early stages of the core pipeline to permit instructions and data to be passed between the two pipelines. The coprocessor runs one pipeline stage behind the core pipeline.

To prevent the coprocessor interface introducing critical paths, wait states can be inserted in external coprocessor operations. These wait states enable critical signals to be retimed.

The VFP unit connects to a separate internal coprocessor interface that has different timings and behavior, using controlled internal interconnection delays.

Chapter 11 *Coprocessor Interface* describes the interface for on-chip coprocessors such as floating-point or other application-specific hardware acceleration units.

1.3.7 Debug

The debug coprocessor, CP14, implements a full range of debug features described in Chapter 13 *Debug* and Chapter 14 *Debug Test Access Port*.

The core provides extensive support for real-time debug and performance profiling.

The following sections describe debug in more detail:

- *System performance monitoring*
- *ETM interface*
- *Real-time debug facilities.*

System performance monitoring

This is a group of counters that you can configure to monitor the operation of the processor and memory system. For more details, see *System performance monitor* on page 3-10.

ETM interface

You can connect an external *Embedded Trace Macrocell* (ETM) unit to the processor for real-time code tracing of the core in an embedded system.

The ETM interface collects various processor signals and drives these signals from the core. The interface is unidirectional and runs at the full speed of the core. The ETM interface connects directly to the external ETM unit without any additional glue logic. You can disable the ETM interface for power saving. For more details, see Chapter 15 *Trace Interface Port*.

Real-time debug facilities

The ARM1156T2F-S processor contains an EmbeddedICE-RT logic unit to provide real-time debug facilities. It has the following capabilities:

- up to six breakpoints
- up to two watchpoints
- *Debug Communications Channel* (DCC).

The EmbeddedICE-RT logic connects directly to the core and monitors the internal address and data buses. You can access the EmbeddedICE-RT logic in one of two ways:

- executing CP14 instructions

- through a JTAG-style interface and associated TAP controller.

The EmbeddedICE-RT logic supports two modes of debug operation:

Halt debug-mode

On a debug event, such as a breakpoint or watchpoint, the debug logic stops the core and forces the core into Debug state. This enables you to examine the internal state of the core, and the external state of the system, independently from other system activity. When the debugging process completes, the core and system state is restored, and normal program execution resumes.

Monitor debug-mode

On a debug event, the core generates a debug exception instead of entering Debug state, as in Halt debug-mode. The exception entry enables a debug monitor program to debug the processor while enabling critical interrupt service routines to operate on the processor. The debug monitor program can communicate with the debug host over the DCC or any other communications interface in the system.

1.3.8 Vector Floating-Point (VFP)

The VFP coprocessor supports floating point arithmetic operations and is a functional block within the ARM1156T2F-S processor. The VFP coprocessor is mapped as coprocessor numbers 10 and 11. Software can determine whether the VFP is present by the use of the Coprocessor Access Control Register. For more details, see *cI*, *Coprocessor Access Control Register* on page 3-53.

———— Note —————

The ARM1156T2-S processor does not include a VFP coprocessor.

For more details, see Chapter 19 *VFP Introduction* to Chapter 23 *VFP Exception Handling*.

IEEE754 compliance

The VFP supports all five floating point exceptions defined by IEEE754:

- invalid operation
- divide by zero
- overflow
- underflow

- inexact.

You can individually enable or disable these exception traps. If disabled, the IEEE754-defined default results are returned. All rounding modes are supported, and basic single and basic double formats are used.

For full compliance, the VFP requires support code to handle arithmetic where operands or results are de-norms. This support code is normally installed on the Undefined instruction exception handler. For more information see *IEEE Standard for Binary Floating-Point Arithmetic*.

Flush-to-zero mode

A flush-to-zero mode is provided where a default treatment of de-norms is applied. Table 1-1 shows the default behavior in flush-to-zero mode.

Table 1-1 Flush-to-zero mode

Operation	Flush-to-zero
De-norm operand(s)	Treated as 0+n Inexact flag set
De-norm result	Returned as 0+n Inexact Flag set

Operations not supported

The following operations are not directly supported by the VFP:

- remainder
- binary (decimal) conversions
- direct comparisons between single and double-precision values.

These are normally implemented as C library functions.

1.3.9 System control coprocessor

The system control coprocessor provides configuration and control of the memory system and its associated functionality. Other system-level operation, such as memory barrier instructions, are also managed through the system control coprocessor.

For more details, see *System control and configuration* on page 3-5.

1.3.10 Interrupt handling

Interrupt handling in the ARM1156T2F-S processor is compatible with previous ARM architectures, but has several additional features to improve interrupt performance for real-time applications.

Whether you have a have a VIC in your design or not, you must ensure that the **nIRQ** and **nFIQ** signals are LOW until the processor has started to execute the interrupt handler.

Interrupt handling is described in more detail in the following sections:

- *VIC port*
- *Low interrupt latency configuration*
- *Interrupt latency configuration control* on page 1-19
- *Exception processing* on page 1-19.

VIC port

The core has a dedicated port that enables an external interrupt controller, like the ARM PrimeCell Vectored Interrupt Controller (VIC), to supply a vector address along with an *interrupt request* (IRQ) signal. This provides faster interrupt entry but you can disable it for compatibility with earlier interrupt controllers.

Low interrupt latency configuration

This mode minimizes the worst-case interrupt latency of the processor, with a small reduction in peak performance, or instructions-per-cycle. You can tune the behavior of the core to suit the requirements of the application.

The low-latency configuration disables HUM operation of the cache. In low-latency mode, on receipt of an interrupt, the ARM1156T2F-S processor:

- abandons any pending restartable memory operations
- restarts memory operations on return from the interrupt.

In low interrupt latency configuration, software must only use multi-word load/store instructions that are fully restartable. The software must not use multi-word load or store instructions on memory locations that produce side-effects for the type of access concerned.

The instructions that this currently applies to are:

ARM	LDC, all forms of LDM, LDRD, and STC, and all forms of STM and STRD.
Thumb	LDMIA, STMIA, PUSH, and POP.

Thumb2 LDC, all forms of LDM, LDRD, and STC, and all forms of STM and STRD.

To achieve optimum interrupt latency, memory locations accessed with these instructions must not have large numbers of wait-states associated with them. To minimize the interrupt latency, the following is recommended:

- multiple accesses to areas of memory marked as Device or Strongly Ordered must not be performed to slow areas of memory because these areas take many cycles to generate a response
- SWP operations must not be performed to slow areas of memory.

Interrupt latency configuration control

Configuration is through the system control coprocessor. To ensure that a change between normal and low interrupt latency configurations is synchronized correctly, you must use software systems that only change the configuration while interrupts are disabled.

Exception processing

The ARMv6 architecture contains exception processing, to reduce interrupt handler entry and exit time:

SRS Save return state to a specified stack frame.

RFE Return from exception.

CPS Change processor state.

For more details, see *Instructions for exception handling* on page 2-21.

1.4 Power management

The ARM1156T2F-S processor includes several microarchitectural features to reduce energy consumption:

- Accurate branch and return prediction, reducing the number of incorrect instruction fetch and decode operations.
- Use of physically tagged caches, which reduce the number of cache flushes and refills, to save energy in the system.
- The caches use sequential access information to reduce the number of accesses to the Tag RAMs and to unmatched data RAMs.
- Extensive use of gated clocks and gates to disable inputs to unused functional blocks. Because of this, only the logic actively in use to perform a calculation consumes any dynamic power.

The ARM1156T2F-S processor uses four levels of power management:

Run mode This mode is the normal mode of operation in which all of the functionality of the ARM1156T2F-S processor is available.

Standby mode

This mode disables most of the clocks of the device, while keeping the device powered up. This reduces the power drawn to the static leakage current, plus a tiny clock power overhead required to enable the device to wake up from the standby mode. The transition from the standby mode to the run mode is caused by one of the following:

- an interrupt, either masked or unmasked
- a debug request, regardless of whether debug is enabled
- reset.

Shutdown mode

This mode has the entire device powered down. All state, including cache and TCM state, must be saved externally. The part is returned to the run state by the assertion of reset. This state saving is performed with interrupts disabled, and finishes with a DrainWriteBuffer operation. The ARM1156T2F-S processor then communicates with the power controller that it is ready to be powered down.

Dormant mode

This mode enables the ARM1156T2F-S processor to be powered down, while leaving the state of the caches and the TCM powered up and maintaining their state. Although software visibility of the valid bits is provided to enable implementation of dormant mode, the following are required for full implementation of dormant mode:

- modification of the RAM blocks to include an input clamp
- implementation of separate power domains.

Power management features are described in more detail in Chapter 10 *Power Control*.

1.5 Configurable options

Table 1-2 shows the configurable features in ARM1156T2F-S processor.

Table 1-2 Configurable options

Feature	Configurable option	Default value
Memory Protection Unit	Yes, or No	Yes
TCM block size	0KB, 4KB, 8KB, 16KB, 32KB, 64KB, 128KB, or 256KB	16KB
ITCM	Yes, or No	Yes
DTCM	Yes, or No	Yes
Cache Way Size	1KB, 2KB, 4KB, 8KB, or 16KB	4KB (4-ways)
Number of cache ways	1, 2, or 4	4
Cache present	Yes, or No	Yes
Cache parity generation and detection	Yes, or No	Yes
Vector Floating Point Unit	Yes, or No	There are two variants of the processor: <ul style="list-style-type: none">ARM1156T2F-S includes a VFPARM1156T2-S does not include a VFP

The number of TCMs are restricted to a minimum to reduce the impact on performance. In addition, the form of the BIST solution for the RAM blocks in the ARM1156T2F-S design is determined when the processor is implemented. For details, see the *ARM1156T2F-S and ARM1156T2-S Implementation Guide*.

1.6 Pipeline stages

The following stages make up the ARM1156T2F-S pipeline:

- three Fetch stages
- a Decode stage
- an Issue stage
- the four stages of the ARM1156T2F-S integer execution pipeline.

Figure 1-3 shows the pipeline stages of the core and the pipeline operations that can be performed at each stage.

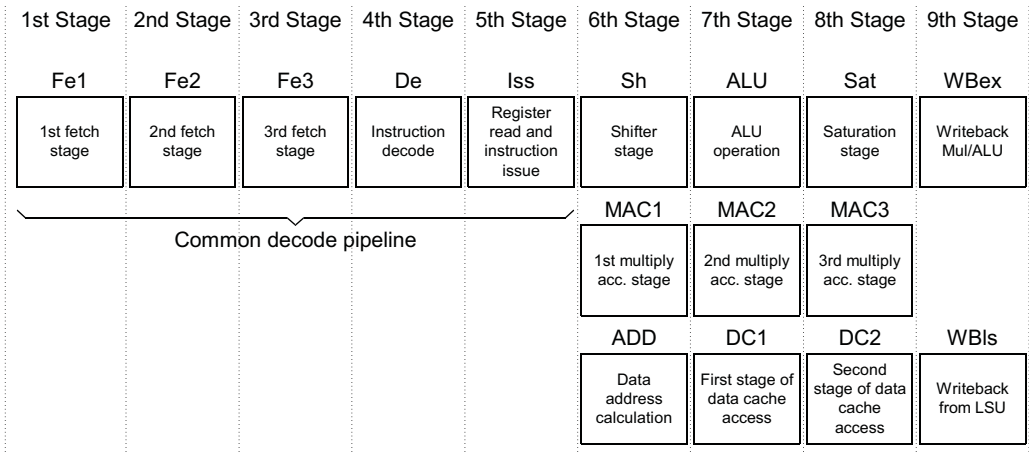

Figure 1-3 ARM1156T2F-S pipeline stages

The pipeline stages are:

- Fe1** First stage of instruction fetch where address is issued to memory.
- Fe2** Second stage of instruction fetch where memory returns data to core.
- Fe3** Third stage of instruction fetch for branch prediction and Thumb-2 instruction alignment.
- De** Instruction decode.
- Iss** Register read and instruction issue.
- Sh** Shifter stage.
- ALU** Main integer operation calculation.
- Sat** Pipeline stage to enable saturation of integer results.

WBex	Write back of data from the multiply or main execution pipelines.
MAC1	First stage of the multiply-accumulate pipeline.
MAC2	Second stage of the multiply-accumulate pipeline.
MAC3	Third stage of the multiply-accumulate pipeline.
ADD	Address generation stage.
DC1	First stage of data cache access.
DC2	Second stage of data cache access.
WBIs	Write back of data from the Load Store Unit.

By overlapping the various stages of operation, the ARM1156T2F-S processor maximizes the clock rate achievable to execute each instruction. It delivers a throughput greater than one instruction for each cycle.

The Fetch stages can hold up to four instructions, where branch prediction is performed on instructions ahead of execution of earlier instructions.

The Issue and Decode stages can contain any instruction in parallel with a predicted branch.

The Execute, Memory, and Write stages can contain a predicted branch, an ALU or multiply instruction, a load/store multiple instruction, and a coprocessor instruction in parallel execution.

1.7 Typical pipeline operations

Figure 1-4 shows all the operations in each of the pipeline stages in the ALU pipeline, the load/store pipeline, and the HUM buffers.

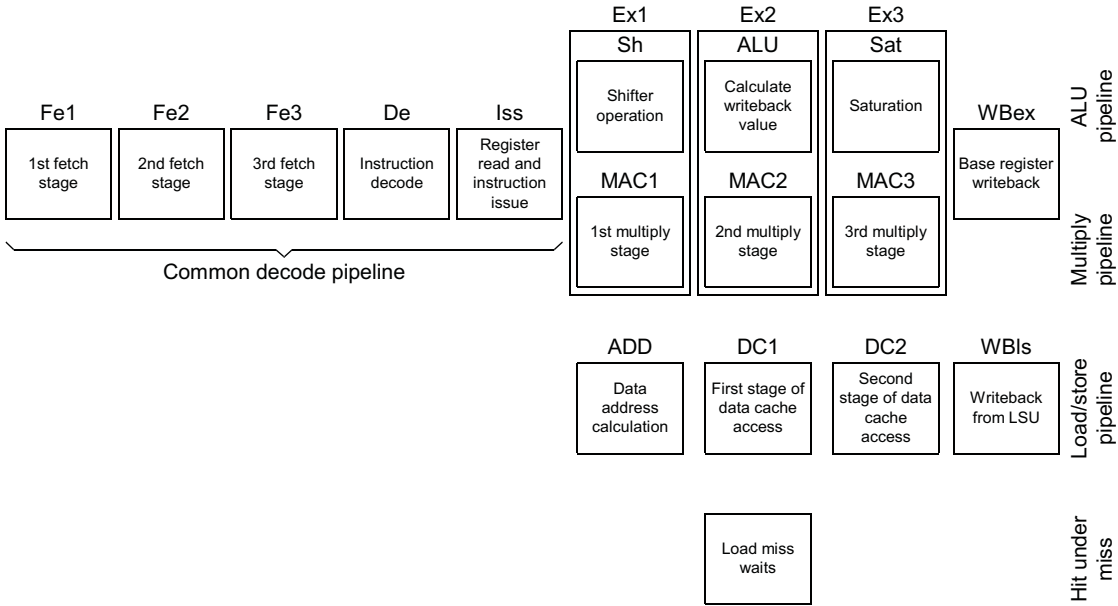

Figure 1-4 Typical operations in pipeline stages

Figure 1-5 shows a typical ALU data processing instruction. The processor does not use the load/store pipeline or the HUM buffer.

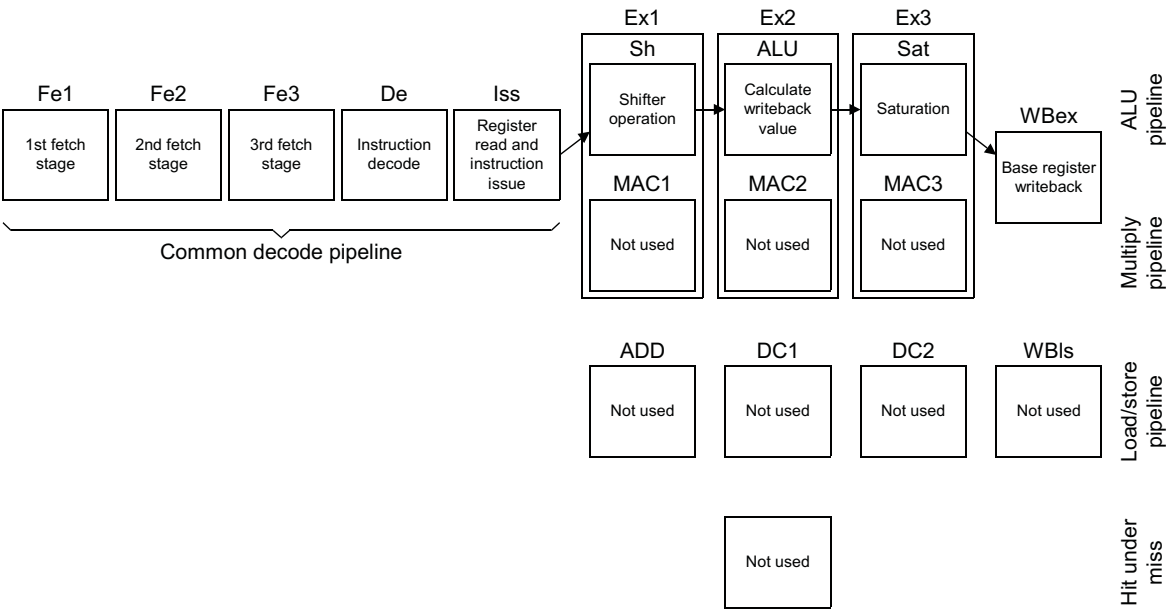

Figure 1-5 Typical ALU operation

Figure 1-6 shows a typical multiply operation. The MUL instruction can loop in the MAC1 stage until it has passed through the first part of the multiplier array enough times. The MUL instruction progresses to MAC2 and MAC3 where it passes once through the second half of the array to produce the final result.

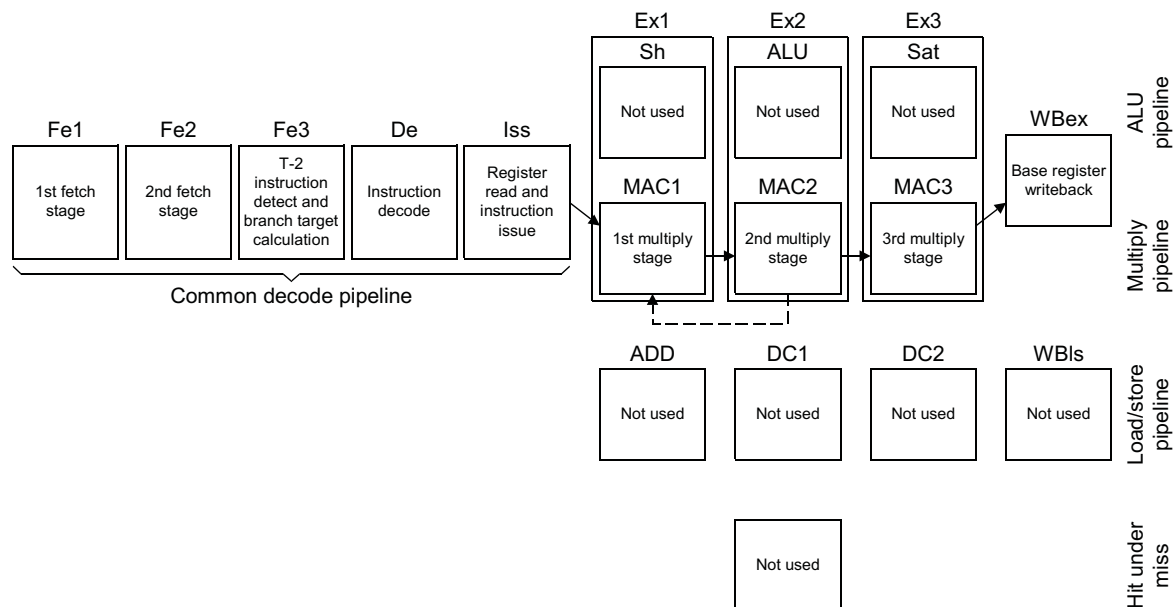

Figure 1-6 Typical multiply operation

1.7.1 Instruction progression

Figure 1-7 shows an LDR/STR operation that hits in the data cache.

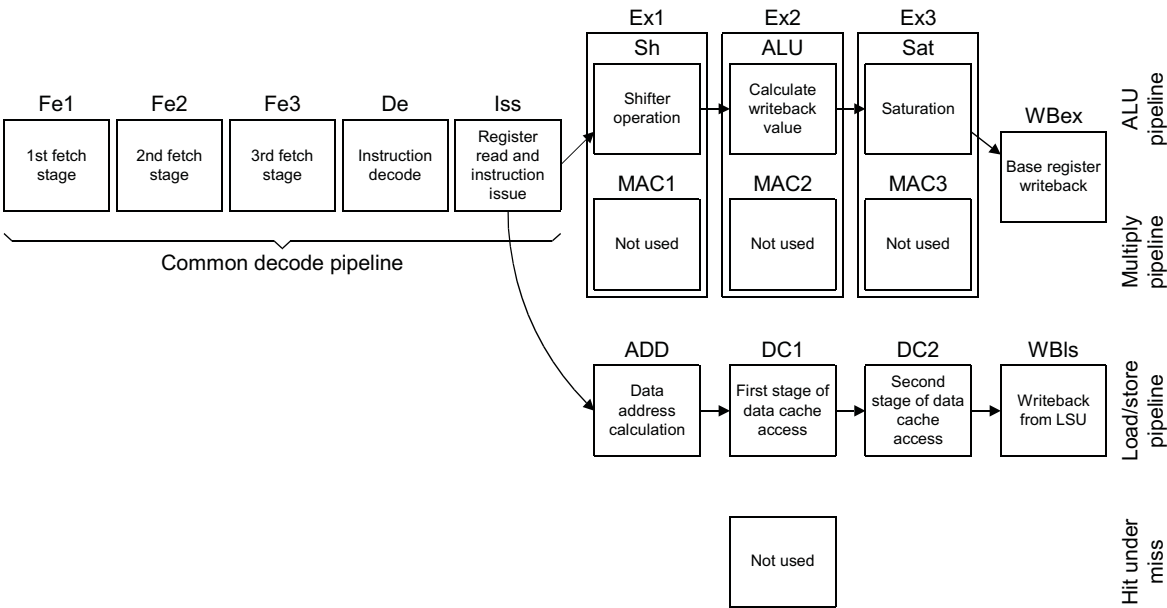

Figure 1-7 Progression of an LDR/STR operation

Figure 1-8 shows the progression of an LDM/STM operation that completes by use of the load/store pipeline. Other instructions can use the ALU pipeline at the same time as the LDM/STM completes in the load/store pipeline.

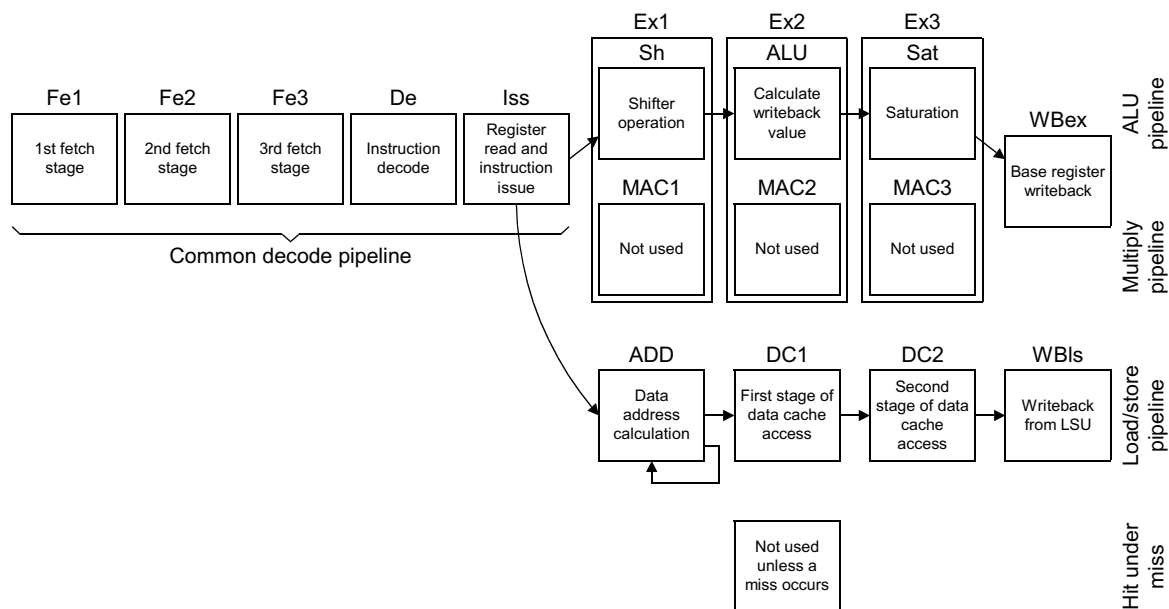

Figure 1-8 Progression of an LDM/STM operation

Figure 1-9 shows the progression of an LDR that misses. When the LDR is in the HUM buffers, other instructions, including independent loads that hit in the cache, can run under it.

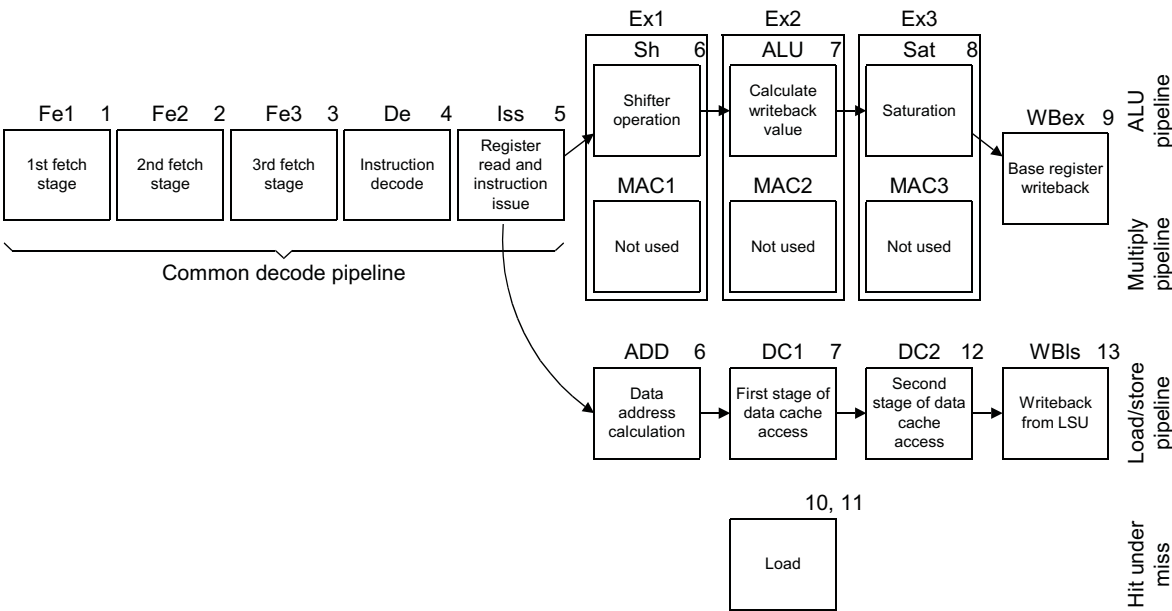

Figure 1-9 Progression of an LDR that misses

For details of instruction cycle timings see Chapter 17 *Cycle Timings and Interlock Behavior*.

1.8 About the architecture

This processor is an implementation of the ARM architecture v6. For details on the ARM and Thumb 2 instruction sets, see the *ARM Architecture Reference Manual*.

Contact ARM Limited for complete descriptions of all instruction sets.

1.9 Product revisions

This manual is for revision r0p4 of the ARM1156T2F-S processor. See *Product revision status* on page xxiv for details of revision numbering.

There are no differences in functionality between the r0p0 and r0p4 product revisions of the processor.

Chapter 2

Programmer's Model

This chapter describes the ARM1156T2F-S registers and provides information for programming the microprocessor. It contains the following sections:

- *About the programmer's model* on page 2-2
- *Processor operating states* on page 2-3
- *Data types* on page 2-5
- *Memory formats* on page 2-6
- *Operating modes* on page 2-4
- *Registers* on page 2-8
- *The program status registers* on page 2-12
- *Exceptions* on page 2-20.
- *Acceleration of execution environments* on page 2-40.

2.1 About the programmer's model

The ARM1156T2F-S processor implements ARM architecture v6 with Thumb-2 extensions:

- 32-bit ARM instruction set
- 16-bit or 32-bit Thumb instruction set.

For more details on the ARM and Thumb-2 extensions instruction sets, see the *ARM Architecture Reference Manual*.

2.2 Processor operating states

The ARM1156T2F-S processor has two operating states:

ARM state	32-bit, word-aligned ARM instructions are executed in this state.
Thumb state	32-bit and 16-bit halfword-aligned Thumb and Thumb-2 instructions.

Note

Transition between ARM state and Thumb state does not affect the processor mode or the register contents.

2.2.1 Switching state

The operating state of the ARM1156T2F-S processor can be switched between ARM state and Thumb state:

- Using the BX and BLX instructions, or by a load to the PC. Switching state is described in the *ARM Architecture Reference Manual*.
- Automatically on an exception. You can write an exception handler routine in ARM or Thumb code. For more details, see *Exceptions* on page 2-20.

2.2.2 Interworking ARM and Thumb state

The ARM1156T2F-S processor enables you to mix ARM and Thumb code. For more details, see the chapter about interworking ARM and Thumb in the *RealView Compilation Tools Developer Guide*.

2.3 Operating modes

In each state there are seven modes of operation:

- User mode is the usual mode for the execution of ARM or Thumb programs, that is it is used for executing most application programs
- *Fast interrupt* (FIQ) mode is used for handling fast interrupts
- *Interrupt* (IRQ) mode is used for general-purpose interrupt handling
- Supervisor mode is a protected mode for the operating system
- Abort mode is entered after a data or instruction abort
- System mode is a privileged user mode for the operating system
- Undefined mode is entered when an undefined instruction exception occurs.

Modes other than User mode are collectively known as privileged modes. Privileged modes are used to service interrupts or exceptions, or to access protected resources.

2.4 Data types

The ARM1156T2F-S processor supports the following data types:

- doubleword (64-bit)
- word (32-bit)
- halfword (16-bit)
- byte (8-bit).

Note

- When any of these types are described as unsigned, the N-bit data value represents a non-negative integer in the range 0 to $+2^N-1$, using normal binary format.
 - When any of these types are described as signed, the N-bit data value represents an integer in the range -2^{N-1} to $+2^{N-1}-1$, using two's complement format.
-

For best performance you must align these as follows:

- doubleword quantities must be aligned to eight-byte boundaries
- word quantities must be aligned to four-byte boundaries
- halfword quantities must be aligned to two-byte boundaries
- byte quantities can be placed on any byte boundary.

The ARM1156T2F-S processor supports mixed-endian and unaligned access. For more details, see Chapter 6 *Unaligned and Mixed-Endian Data Access Support*.

Note

You cannot use LDRD, LDM, LDC, STRD, STM, or STC instructions to access 32-bit quantities if they are not 32-bit aligned.

2.5 Memory formats

The ARM1156T2F-S processor views memory as a linear collection of bytes numbered in ascending order from zero. Bytes 0-3 hold the first stored word, and bytes 4-7 hold the second stored word, for example.

The ARM1156T2F-S processor can treat words in memory as being stored in either:

- 32-bit word-invariant big-endian format
- Little-endian format.

Additionally, the ARM1156T2F-S processor supports mixed-endian and unaligned data accesses. For more details, see the *Architecture Reference Manual*.

2.5.1 32-bit word-invariant big-endian format

In 32-bit word-invariant big-endian format, the ARM1156T2F-S processor stores the most significant byte of a word at the lowest-numbered byte, and the least significant byte at the highest-numbered byte. Therefore, byte 0 of the memory system connects to data lines 31-24. This is shown in Figure 2-1.

- Most significant byte is at lowest address
- Word is addressed by byte address of most significant byte

Figure 2-1 Big-endian addresses of bytes within words

2.5.2 Little-endian format

In little-endian format, the lowest-numbered byte in a word is the least significant byte of the word and the highest-numbered byte is the most significant. Therefore, byte 0 of the memory system connects to data lines 7-0. This is shown in Figure 2-2 on page 2-7.

- Least significant byte is at lowest address
- Word is addressed by byte address of least significant byte

Figure 2-2 Little-endian addresses of bytes within words

2.6 Registers

The ARM1156T2F-S processor has a total of 37 registers:

- 31 general-purpose 32-bit registers
- six 32-bit status registers.

These registers are not all accessible at the same time. The processor state and operating mode determine which registers are available to the programmer.

2.6.1 The register set

In the ARM1156T2F-S processor the register set is used in both the ARM and Thumb states. Sixteen general registers and one or two status registers are accessible at any time. In privileged modes, mode-specific banked registers become available. Figure 2-3 on page 2-10 shows which registers are available in each mode.

The register set contains 16 directly-accessible registers, r0-r15. Another register, the *Current Program Status Register* (CPSR), contains condition code flags, status bits, and current mode bits. Registers r0-r13 are general-purpose registers used to hold either data or address values. Registers r14, r15, and the CPSR have the following special functions:

Link Register Register r14 is used as the subroutine *Link Register* (LR). Register r14 receives the return address when a *Branch with Link* (BL or BLX) instruction is executed. You can treat r14 as a general-purpose register at all other times. The corresponding banked registers r14_svc, r14_irq, r14_fiq, r14_abt, and r14_und are similarly used to hold the return values when interrupts and exceptions arise, or when BL or BLX instructions are executed within interrupt or exception routines.

Program Counter Register r15 holds the PC:

- in ARM state this is word-aligned
- in Thumb state this is either word or halfword-aligned.

———— **Note** ————

There are special cases for reading R15:

- reading the address of the current instruction plus 4
- reading 0x00000000 (zero).

There are special cases for writing R15:

- causing a branch to the address that was written to R15
- ignoring the value that was written to R15

- writing bits [31:28] of the value that was written to R15 to the condition flags, and ignoring bits [27:0] (used for the MRC instruction only).

None of these special cases must be assumed unless it is explicitly stated in the instruction description. Instead, instructions with register fields equal to R15 must be treated as UNPREDICTABLE.

For more details, see the *ARM Architecture Reference Manual*.

In privileged modes, another register, the *Saved Program Status Register* (SPSR), is accessible. This contains the condition code flags, status bits, and current mode bits saved as a result of the exception that caused entry to the current mode.

Banked registers have a mode identifier that indicates which mode they relate to. These mode identifiers are listed in Table 2-1.

Table 2-1 Register mode identifiers

Mode	Mode identifier
User	usr ^a
Fast interrupt	fiq
Interrupt	irq
Supervisor	svc
Abort	abt
System	usr ^a
Undefined	und

- a. The *usr* identifier is usually omitted from register names. It is only used in descriptions where the User or System mode register is specifically accessed from another operating mode.

FIQ mode has seven banked registers mapped to r8-r14 (r8_fiq-r14_fiq). As a result many FIQ handlers do not have to save any registers.

The Supervisor, Abort, IRQ, and Undefined modes each have alternative mode-specific registers mapped to r13 and r14, permitting a private stack pointer and link register for each mode.

Figure 2-3 on page 2-10 shows the register set.

General registers and program counter

System and User	FIQ	Supervisor	Abort	IRQ	Undefined
r0	r0	r0	r0	r0	r0
r1	r1	r1	r1	r1	r1
r2	r2	r2	r2	r2	r2
r3	r3	r3	r3	r3	r3
r4	r4	r4	r4	r4	r4
r5	r5	r5	r5	r5	r5
r6	r6	r6	r6	r6	r6
r7	r7	r7	r7	r7	r7
r8	 r8_fiq	r8	r8	r8	r8
r9	 r9_fiq	r9	r9	r9	r9
r10	 r10_fiq	r10	r10	r10	r10
r11	 r11_fiq	r11	r11	r11	r11
r12	 r12_fiq	r12	r12	r12	r12
r13	 r13_fiq	 r13_svc	 r13_abt	 r13_irq	 r13_und
r14	 r14_fiq	 r14_svc	 r14_abt	 r14_irq	 r14_und
r15	r15 (PC)	r15 (PC)	r15 (PC)	r15 (PC)	r15 (PC)

Program status registers

CPSR	CPSR	CPSR	CPSR	CPSR	CPSR
	 SPSR_fiq	 SPSR_svc	 SPSR_abt	 SPSR_irq	 SPSR_und

 = banked register

Figure 2-3 Register organization

Figure 2-4 on page 2-11 shows an alternative view of the registers.

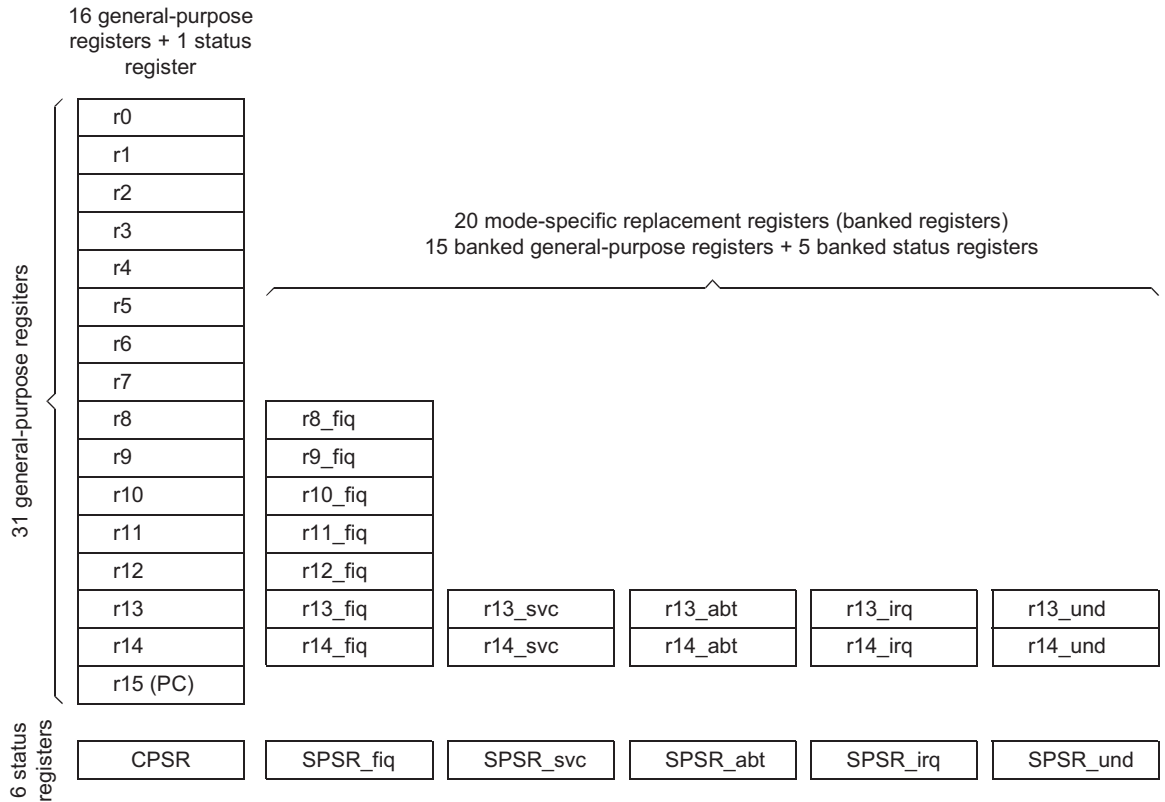

Figure 2-4 ARM1156T2F-S register set showing banked registers

Note

For 16-bit Thumb instructions, the high registers, r8-r15, are not part of the standard register set. You can use special variants of the MOV instruction to transfer a value from a low register, in the range r0-r7, to a high register, and from a high register to a low register. The CMP instruction enables you to compare high register values with low register values. The ADD instruction enables you to add high register values to low register values. For more details, see the *ARM Architecture Reference Manual*.

2.7 The program status registers

The ARM1156T2F-S processor contains one CPSR, and five SPSRs for exception handlers to use. The purpose of the program status registers is to:

- hold information about the most recently performed ALU operation
- control the enabling and disabling of interrupts
- set the processor operating mode.

Figure 2-5 shows the bit arrangement in the status registers. For more details on the status register bits, see *Execution state bits* on page 2-13 to *Reserved bits* on page 2-18.

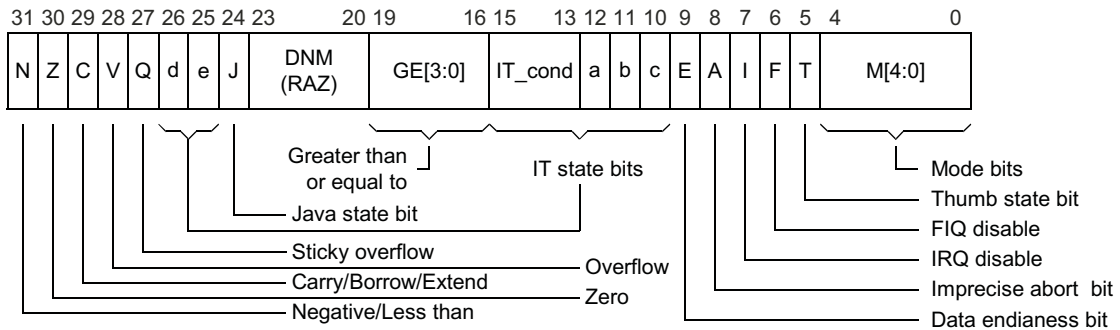

Figure 2-5 Program status register

2.7.1 The condition code flags

The N, Z, C, and V bits are the condition code flags. You can set them by arithmetic and logical operations, and also by MSR and LDM instructions. The ARM1156T2F-S processor tests these flags to determine whether to execute an instruction.

In ARM state, most instructions can execute conditionally on the state of the N, Z, C, and V bits. The exceptions are:

- BKPT
- CDP2
- CPS
- LDC2
- MCR2
- MCRR2
- MRC2
- MRRC2
- PLD

- SETEND
- RFE
- SRS
- STC2.

In Thumb state, only the Branch instruction is conditional. Other instructions can be made conditional by placing them in the *If-Then* (IT) block. For more details about conditional execution, see the *ARM Architecture Reference Manual*.

2.7.2 The Q flag

The Sticky Overflow, Q, flag can be set by certain multiply and fractional arithmetic instructions:

- QADD
- QDADD
- QSUB
- QDSUB
- SMLAD
- SMLAxy
- SMLAWy
- SMLSD
- SMUAD
- SSAT
- SSAT16
- USAT
- USAT16.

The Q flag is sticky in that, when set by an instruction, it remains set until explicitly cleared by an MSR instruction writing to the CPSR. Instructions cannot execute conditionally on the status of the Q flag.

To determine the status of the Q flag you must read the PSR into a register and extract the Q flag from this. For details of how the Q flag is set and cleared, see individual instruction definitions in the *ARM Architecture Reference Manual*.

2.7.3 Execution state bits

The execution state bits consist of the If-Then state bits, IT, Java state bit, J, and Thumb state bit, T.

IT state bits

The IT_cond field encodes the base condition code for the current IT block, if any. It must contain b000 when no IT block is active.

The a, b, c, d, and e bits encode the number of instructions that are to be conditionally executed, and whether the condition for each is the base condition code or the inverse of the base condition code. They must contain b00000 when no IT block is active.

When an IT instruction is executed, these bits are set according to the condition in the instruction, and the *Then* and *Else* (T and E) parameters in the instruction.

During execution of an IT block, the a, b, c, d, and e bits are shifted:

- to reduce the number of instructions to be conditionally executed by one
- to move the next bit into position to form the least significant bit of the condition code.

Table 2-2 shows how the IT execution state bits operate.

Table 2-2 Shifting of IT execution state bits

Old state						New state					
IT_cond	a	b	c	d	e	IT_cond	a	b	c	d	e
cond_base	P1	P2	P3	P4	1	cond_base	P2	P3	P4	1	0
cond_base	P1	P2	P3	1	0	cond_base	P2	P3	1	0	0
cond_base	P1	P2	1	0	0	cond_base	P2	1	0	0	0
cond_base	P1	1	0	0	0	b000	0	0	0	0	0

Table 2-3 shows the effect of each state.

Table 2-3 Effect of IT execution state bits

Entry point for:	IT_cond	a	b	c	d	e	Description
4-instruction IT block	cond_base	P1	P2	P3	P4	1	Next instruction has condition cond_base, P1
3-instruction IT block	cond_base	P1	P2	P3	1	0	Next instruction has condition cond_base, P1
2-instruction IT block	cond_base	P1	P2	1	0	0	Next instruction has condition cond_base, P1
1-instruction IT block	cond_base	P1	1	0	0	0	Next instruction has condition cond_base, P1

Table 2-3 Effect of IT execution state bits (continued)

Entry point for:	IT_cond	a	b	c	d	e	Description
Invalid	non-zero	x	0	0	0	0	Unpredictable
Invalid	bxxx	1	0	0	0	0	Unpredictable
Not in an IT block	b000	0	0	0	0	0	Normal execution

Note

- The IT state bits return as zero if an MRS of the CPSR is executed within an IT block in normal operation. In Debug state an MRS of the CPSR within an IT block return the IT state bits as shown in Table 2-2 on page 2-14 and Table 2-3 on page 2-14
- Writing the IT bits by MSR instructions is ignored.

In Debug state an MRS of the CPSR within an IT block return the IT state bits as shown in Table 2-2 on page 2-14 and Table 2-3 on page 2-14.

For more details, see the *ARM Architecture Reference Manual*.

J bit

This bit is set to 0 on reset. For information on its behavior, see *Acceleration of execution environments* on page 2-40.

T bit

The T bit reflects the operating state:

- when the T bit is set, the processor is executing in Thumb state
- when the T bit is clear, the processor is executing in ARM state.

Note

Never use an MSR instruction to force a change to the state of the T bit in the CPSR. If an MSR instruction does try to modify this bit the result is architecturally Unpredictable. In the ARM1156T2F-S processor this bit is not affected.

2.7.4 Do Not Modify bits

Software must not modify the *Do Not Modify* (DNM), *Read As Zero* (RAZ) bits. These bits are:

- Readable, to preserve the state of the processor, for example, during process context switches
- Writable, to enable the processor to restore its state. To maintain compatibility with future ARM processors, and as good practice, you are strongly advised to use a read-modify-write strategy when you change the CPSR.

2.7.5 The GE[3:0] bits

Some of the SIMD instructions set GE[3:0] as greater-than-or-equal bits for individual halfwords or bytes of the result, as shown in Table 2-4.

Table 2-4 GE[3:0] settings

	GE[3]	GE[2]	GE[1]	GE[0]
Instruction	A op B > C	A op B > C	A op B > C	A op B > C
Signed				
SADD16	$[31:16] + [31:16] \geq 0$	$[31:16] + [31:16] \geq 0$	$[15:0] + [15:0] \geq 0$	$[15:0] + [15:0] \geq 0$
SSUB16	$[31:16] - [31:16] \geq 0$	$[31:16] - [31:16] \geq 0$	$[15:0] - [15:0] \geq 0$	$[15:0] - [15:0] \geq 0$
SASX	$[31:16] + [15:0] \geq 0$	$[31:16] + [15:0] \geq 0$	$[15:0] - [31:16] \geq 0$	$[15:0] - [31:16] \geq 0$
SSAX	$[31:16] - [15:0] \geq 0$	$[31:16] - [15:0] \geq 0$	$[15:0] + [31:16] \geq 0$	$[15:0] + [31:16] \geq 0$
SADD8	$[31:24] + [31:24] \geq 0$	$[23:16] + [23:16] \geq 0$	$[15:8] + [15:8] \geq 0$	$[7:0] + [7:0] \geq 0$
SSUB8	$[31:24] - [31:24] \geq 0$	$[23:16] - [23:16] \geq 0$	$[15:8] - [15:8] \geq 0$	$[7:0] - [7:0] \geq 0$
Unsigned				
UADD16	$[31:16] + [31:16] \geq 2^{16}$	$[31:16] + [31:16] \geq 2^{16}$	$[15:0] + [15:0] \geq 2^{16}$	$[15:0] + [15:0] \geq 2^{16}$
USUB16	$[31:16] - [31:16] \geq 0$	$[31:16] - [31:16] \geq 0$	$[15:0] - [15:0] \geq 0$	$[15:0] - [15:0] \geq 0$
UASX	$[31:16] + [15:0] \geq 2^{16}$	$[31:16] + [15:0] \geq 2^{16}$	$[15:0] - [31:16] \geq 0$	$[15:0] - [31:16] \geq 0$
USAX	$[31:16] - [15:0] \geq 0$	$[31:16] - [15:0] \geq 0$	$[15:0] + [31:16] \geq 2^{16}$	$[15:0] + [31:16] \geq 2^{16}$
UADD8	$[31:24] + [31:24] \geq 2^8$	$[23:16] + [23:16] \geq 2^8$	$[15:8] + [15:8] \geq 2^8$	$[7:0] + [7:0] \geq 2^8$
USUB8	$[31:24] - [31:24] \geq 0$	$[23:16] - [23:16] \geq 0$	$[15:8] - [15:8] \geq 0$	$[7:0] - [7:0] \geq 0$

Note

GE bit is 1 if $A \text{ op } B \geq C$, otherwise 0.

The SEL instruction uses GE[3:0] to select which source register supplies each byte of its result.

Note

- For unsigned operations, the GE bits are determined by the usual ARM rules for carries out of unsigned additions and subtractions, and so are carry-out bits.
 - For signed operations, the rules for setting the GE bits are chosen so that they have the same sort of greater than or equal functionality as for unsigned operations.
-

2.7.6 The E bit

ARM and Thumb instructions are provided to set and clear the E bit. The E bit controls load/store endianness. For details of where the E bit is used, see the *ARM Architecture Reference Manual*.

Architecture versions prior to ARMv6 specify this bit as SBZ. This ensures no endianness reversal on loads or stores.

2.7.7 The A bit

The A bit is set automatically. It is used to disable imprecise Data Aborts. For more details of how to use the A bit see *Imprecise Data Abort mask in the CPSR/SPSR* on page 2-35.

2.7.8 Interrupt disable bits

The I and F bits are the interrupt disable bits:

- when the I bit is set, IRQ interrupts are disabled
- when the F bit is set, FIQ interrupts are disabled.

2.7.9 Mode bits

Caution

An illegal value programmed into M[4:0] causes the processor to enter an unrecoverable state. If this occurs, you must apply reset. Not all combinations of the mode bits define a valid processor mode, so take care to use only those bit combinations shown.

M[4:0] are the mode bits. These bits determine the processor operating mode as shown in Table 2-5.

Table 2-5 PSR mode bit values

M[4:0]	Mode	Visible state registers	
		Thumb	ARM
b10000	User	r0-r7, r8-r12 ^a , SP, LR, PC, CPSR	r0-r14, PC, CPSR
b10001	FIQ	r0-r7, r8_fiq-r12_fiq ^a , SP_fiq, LR_fiq PC, CPSR, SPSR_fiq	r0-r7, r8_fiq-r14_fiq, PC, CPSR, SPSR_fiq
b10010	IRQ	r0-r7, r8-r12 ^a , SP_irq, LR_irq, PC, CPSR, SPSR_irq	r0-r12, r13_irq, r14_irq, PC, CPSR, SPSR_irq
b10011	Supervisor	r0-r7, r8-r12 ^a , SP_svc, LR_svc, PC, CPSR, SPSR_svc	r0-r12, r13_svc, r14_svc, PC, CPSR, SPSR_svc
b10111	Abort	r0-r7, r8-r12 ^a , SP_abt, LR_abt, PC, CPSR, SPSR_abt	r0-r12, r13_abt, r14_abt, PC, CPSR, SPSR_abt
b11011	Undefined	r0-r7, r8-r12 ^a , SP_und, LR_und, PC, CPSR, SPSR_und	r0-r12, r13_und, r14_und, PC, CPSR, SPSR_und
b11111	System	r0-r7, r8-r12 ^a , SP, LR, PC, CPSR	r0-r14, PC, CPSR

a. Access to these registers is limited in Thumb state.

2.7.10 Reserved bits

The remaining bits in the PSRs are unused, but are reserved. When changing a PSR flag or control bits, make sure that these reserved bits are not altered. You must ensure that your program does not rely on reserved bits containing specific values because future processors might use some or all of the reserved bits.

2.7.11 Modification of PSR bits by MSR instructions

In previous architecture versions, MSR instructions can modify the flags byte, bits [31:24], of the CPSR in any mode, but the other three bytes are only modifiable in privileged modes.

After the introduction of ARM architecture v6, however, each CPSR bit falls into one of the following categories:

- Bits that are freely modifiable from any mode, either directly by MSR instructions or by other instructions whose side-effects include writing the specific bit or writing the entire CPSR.
Bits in Figure 2-5 on page 2-12 that are in this category are N, Z, C, V, Q, GE[3:0], and E.
- Bits that must never be modified by an MSR instruction, and so must only be written as a side-effect of another instruction. If an MSR instruction does try to modify these bits the results are architecturally Unpredictable. In the ARM1156T2F-S processor these bits are not affected.
The bits in Figure 2-5 on page 2-12 that are in this category are the execution state bits [24, 15:10, 5].
- Bits that can only be modified from privileged modes, and that are completely protected from modification by instructions while the processor is in User mode. The only way that these bits can be modified while the processor is in User mode is by entering a processor exception, as described in *Exceptions* on page 2-20.
Bits in Figure 2-5 on page 2-12 that are in this category are A, I, F, and M[4:0].

2.8 Exceptions

Exceptions occur whenever the normal flow of a program has to be halted temporarily. For example, to service an interrupt from a peripheral. Before attempting to handle an exception, the ARM1156T2F-S processor preserves the current processor state so that the original program can resume when the handler routine has finished.

Exception priorities on page 2-39 describes how the exceptions are dealt with in the fixed order if two or more exceptions occur simultaneously.

This section provides details of the ARM1156T2F-S exception handling:

- *Exception entry and exit summary* on page 2-22
- *Entering an exception* on page 2-23
- *Leaving an exception* on page 2-23.

Several enhancements are made in ARM architecture v6 to the exception model, mostly to improve interrupt latency, as follows:

- New instructions are added to give a choice of stack to use for storing the exception return state after exception entry, and to simplify changes of processor mode and the disabling and enabling of interrupts.
- The interrupt vector definitions on ARMv6 are changed to support the addition of hardware to prioritize the interrupt sources and to look up the start vector for the related interrupt handling routine.
- A low interrupt latency configuration is added in ARMv6. In terms of the instruction set architecture, it specifies that multi-access load/store instructions can be interrupted and then restarted after the interrupt has been processed:
ARM LDC, LDM, LDRD, STC, STM, and STRD,
Thumb LDC, LDM, LDRD, STC, STM, STRD, LDM, POP, and PUSH.
- Support for an imprecise Data Abort that behaves as an interrupt rather than as an abort, in that it occurs asynchronously relative to the instruction execution. Support involves the masking of a pending imprecise Data Abort at times when entry into Abort mode is deemed unrecoverable.
- Exception handling in ARM or Thumb state set by the TE Bit, bit [30], CP15 register c1. For more details, see *c1, Control Register* on page 3-46.

2.8.1 Changes to existing interrupt vectors

In ARMv5, the IRQ and FIQ exception vectors are fixed. Interrupt handlers typically have to start with an instruction sequence to determine the cause of the interrupt and branch to a routine to handle it.

On the ARM1156T2F-S processor the IRQ exception can be determined directly from the value presented on the *Vectored Interrupt Controller* (VIC) port. The vector interrupt behavior is explicitly enabled when the VE bit in CP15 c1 is set. See Chapter 12 *Vectored Interrupt Controller Port*.

An example of a hardware block that can interface to the VIC port is the PrimeCell VIC (PL192), which is available from ARM Limited. This takes a set of inputs from various interrupt sources, prioritizes them, and presents the interrupt type of the highest-priority interrupt being requested and the address of its handler to the processor core. The VIC also masks any lower priority interrupts. Such hardware reduces the time taken to enter the handling routine for the required interrupt.

2.8.2 Instructions for exception handling

This section describes the instructions added to accelerate the handling of exceptions. Full details of these instructions are given in the *ARM Architecture Reference Manual*.

Note

These instructions are available in both ARM and Thumb states.

Store Return State

The *Store Return State* (SRS) instruction stores r14_<current_mode> and spsr_<current_mode> to sequential addresses, and uses the banked version of r13 for a specified mode to supply the base address, and to write back to if you specify base register write-back. This enables an exception handler to store its return state on a stack other than the one automatically selected by its exception entry sequence.

The addressing mode used is a version of ARM addressing mode 4, see the *ARM Architecture Reference Manual*, modified to assume a {r14,SPSR} register list, rather than the use of a list specified by a bit mask in the instruction. This enables the SRS instruction to access stacks in a manner compatible with the normal use of STM instructions for stack accesses.

Return From Exception

The *Return From Exception* (RFE) instruction loads the PC and CPSR from sequential addresses. RFE returns the processor from an exception for which an SRS instruction has saved the return state, see *Store Return State*, and again uses a version of ARM addressing mode 4, modified this time to assume a {PC,CPSR} register list.

Change Processor State

The *Change Processor State* (CPS) instruction provides new values for the CPSR interrupt masks, mode bits, or both, and shortens and speeds up the read/modify/write instruction sequence that ARMv5 uses to perform such tasks. Together with the SRS instruction, CPS enables an exception handler to save its return information on the stack of another mode and then switch to that other mode, without modifications to the stack that belongs to the original mode or any registers other than the new mode stack pointer.

The CPS instruction also streamlines how the processor handles interrupt masks and mode switches in other code. In particular this instruction enables you to efficiently make short code sequences atomic in a uniprocessor system by use of an interrupt disable at the start of the sequence and a interrupt enable at the end of the sequence.

2.8.3 Exception entry and exit summary

Table 2-6 summarizes the PC value preserved in the relevant r14 on exception entry, and the recommended instruction for exiting the exception handler.

Table 2-6 Exception entry and exit

Exception or entry	Recommended return instruction	Previous state		Notes
		ARM r14_x	Thumb r14_x	
SVC	MOVS PC, R14_svc	PC + 4	PC+2	Where the PC is the address of the SVC or undefined instruction.
UNDEF	MOVS PC, R14_und	PC + 4	PC+2	
PABT	SUBS PC, R14_abt, #4	PC + 4	PC+4	Where the PC is the address of instruction that had the Prefetch Abort.
FIQ	SUBS PC, R14_fiq, #4	PC + 4	PC+4	Where the PC is the address of the instruction that was not executed because the FIQ or IRQ took priority.
IRQ	SUBS PC, R14_irq, #4	PC + 4	PC+4	
DABT	SUBS PC, R14_abt, #8	PC + 8	PC+8	Where the PC is the address of the Load or Store instruction that generated the Data Abort.
RESET	NA	-	-	The value saved in r14_svc on reset is Unpredictable.
BKPT	SUBS PC, R14_abt, #4	PC + 4	PC+4	Software breakpoint.

2.8.4 Entering an exception

When handling an exception the ARM1156T2F-S processor:

1. Preserves the address of the next instruction in the appropriate LR. When the exception entry is from:

ARM state:

The ARM1156T2F-S processor writes the value of the PC into the LR, offset by a value (current PC + 4 or PC + 8 depending on the exception) that causes the program to resume from the correct place on return

Thumb state:

The ARM1156T2F-S processor writes the value of the PC into the LR, offset by a value (current PC + 2, PC + 4 or PC + 8 depending on the exception) that causes the program to resume from the correct place on return.

2. Copies the CPSR into the appropriate SPSR. Depending on the exception type, the processor might modify the IT execution state bits of the CPSR prior to this operation to facilitate a return from the exception.
3. Forces the CPSR mode bits to a value that depends on the exception and clears the IT execution state bits in the CPSR.
4. Forces the PC to fetch the next instruction from the relevant exception vector.

The ARM1156T2F-S processor can also set the interrupt disable flags to prevent otherwise unmanageable nesting of exceptions.

ARM state or Thumb state can enter, handle, and exit exceptions. At reset the **TEINIT** pin controls the state used to manage exceptions.

2.8.5 Leaving an exception

When an exception has completed, the exception handler must move the LR, minus an offset to the PC. The offset varies according to the type of exception, as shown in Table 2-6 on page 2-22.

Typically the return instruction is an arithmetic or logical operation with the S bit set and rd = r15, so the core copies the SPSR back to the CPSR.

Note

The action of restoring the CPSR from the SPSR:

- Automatically restores the T, A, I, and F bits to the value they held immediately prior to the exception.
- Normally resets the IT execution state bits to the values held immediately prior to the exception. If the exception handler wants to return to the following instruction these bits might have to be manually advanced to avoid applying the incorrect condition codes to that instruction. For more details of the IT instruction and Undefined instruction and an example exception handler code see the *ARM Architecture Reference Manual*.

Because SVC handlers are always expected to return after the SVC instruction the IT execution state bits are automatically advanced on exception entry prior to copying the CPSR into the SPSR.

2.8.6 Reset

When the **nRESETIN** signal is driven LOW a reset occurs, and the ARM1156T2F-S processor abandons the executing instruction.

When **nRESETIN** is driven HIGH again the ARM1156T2F-S processor:

1. Forces CPSR M[4:0] to b10011 (Supervisor mode), sets the A, I, and F bits in the CPSR. The E bit is set based on the state of the **BIGENDINIT** and **UBITINIT** pins. Other bits in the CPSR are indeterminate.
2. Forces the PC to fetch the next instruction from the reset vector address.
3. Reverts to ARM state or Thumb state depending on the state of the **TEINIT** pin, and resumes execution.

After reset, all register values except the PC and CPSR are indeterminate.

See Chapter 9 *Clocking and Resets* for more details of the reset behavior for the ARM1156T2F-S processor.

2.8.7 Fast interrupt request

The *Fast Interrupt Request* (FIQ) is another exception source that reduces the execution time of the exception handler. In ARM state, FIQ mode has eight private registers to reduce, or even remove the requirement for register saving, minimizing the overhead of context switching.

An FIQ is externally generated by taking the **nFIQ** signal input LOW. You must ensure that the **nFIQ** input is held LOW until the processor acknowledges the interrupt request, from the software handler.

Irrespective of whether exception entry is from ARM state or Thumb state, an FIQ handler returns from the interrupt by executing:

```
SUBS PC,R14_fiq,#4
```

You can disable FIQ exceptions within a privileged mode by setting the CPSR F flag. When the F flag is clear, the ARM1156T2F-S processor checks for a LOW level on the output of the nFIQ register at the end of each instruction.

Note

The CPSR F flag cannot be set for the *Non-maskable Interrupt* (NMI).

FIQs and IRQs are disabled when an FIQ occurs. You can use nested interrupts but it is up to you to save any corruptible registers and to re-enable FIQs and interrupts.

2.8.8 Interrupt request

The IRQ exception is a normal interrupt caused by a LOW level on the **nIRQ** input. IRQ has a lower priority than FIQ, and is masked on entry to an FIQ sequence. You must ensure that the **nIRQ** input is held LOW until the processor acknowledges the interrupt request, either from the VIC interface or the software handler.

Irrespective of whether exception entry is from ARM state or Thumb state an IRQ handler returns from the interrupt by executing:

```
SUBS PC,R14_irq,#4
```

You can disable IRQ exceptions within a privileged mode by setting the CPSR I flag. When the I flag is clear, the ARM1156T2F-S processor checks for a LOW level on the output of the nIRQ register at the end of each instruction.

IRQs are disabled when an IRQ occurs. You can use nested interrupts but it is up to you to save any corruptible registers and to re-enable IRQs.

2.8.9 Low interrupt latency configuration

The purpose of this configuration is to reduce the interrupt latency of the ARM1156T2F-S processor. The FI bit, bit 21, in CP15 c1 is used to enable a low interrupt latency configuration.

This mode:

- disables *Hit-Under-Miss* (HUM) functionality
- abandons restartable external accesses so that the core can react to a pending interrupt faster than is normally the case
- detects low-latency interrupts as early as possible in the main pipeline.

To change between normal and low interrupt latency configurations the sequence to use is:

1. Drain Write Buffer.
2. Change FI Bit.
3. Drain Write Buffer with interrupt disabled.

This sequence ensures that the change is synchronous.

You must ensure that software systems only change the FI bit shortly after reset, while interrupts are disabled. To minimize the interrupt latency in low interrupt latency mode, avoid the use of multi-word load/store instructions to memory locations that are marked as Device or Strongly Ordered. Multi-word accesses to Device or Strongly Ordered memory are not restartable and therefore must complete before the processor can take an interrupt.

Non-device memory enables these instructions to be interruptible when in low interrupt latency configuration. If the instruction is interrupted before it is complete, the result might be that one or more of the words are accessed twice. This is inconsequential.

———— **Note** ————

A similar requirement for instructions to be restartable already exists for unaligned and multi-word load/store instructions in normal configuration. This occurs when these instructions access memory locations that can abort in a recoverable way. If an abort occurs during an access to one of the words in the multi-word operation then the processor executes the abort handler. After the cause of the abort is fixed the abort handler returns to that instruction, and it is restarted. The effect is that multi-word load/store instruction can access the same word twice. Once before the abort was detected, and again when the instruction is restarted.

The requirement in this case is either:

- all side-effects are inconsequential
- the abort must either occur on the first word accessed or not at all.

The instructions that this rule currently applies to are:

- ARM instructions LDC, all forms of LDM, LDRD, STC, all forms of STM, STRD, and unaligned LDR, STR, LDRH, and STRH

- Thumb instructions LDMDB, LDMIA, PUSH, POP, STMDB, and STMIA, and unaligned LDR, LDMDB, STR, and STRH.

You are also advised that, to achieve the best possible interrupt latency, memory locations that these instructions access must not have large numbers of wait-states associated with them.

2.8.10 Interrupt latency example

This section gives an extended example to show how the combination of new facilities improves interrupt latency. The example is not necessarily entirely realistic, but illustrates the main points. The assumptions made are:

1. *Vector Interrupt Controller (VIC)* hardware exists to prioritize interrupts and to supply the address of the highest priority interrupt to the processor core on demand. In the ARMv5 system, the address is supplied in a memory-mapped I/O location, and loading it acts as an entering interrupt handler acknowledgement to the VIC. In the ARMv6 system, the address is loaded and the acknowledgement given automatically, as part of the interrupt entry sequence. In both systems, a store to a memory-mapped I/O location is used to send a finishing interrupt handler acknowledgement to the VIC.
2. The system has the following layers:

Real-time layer

Contains handlers for a number of high-priority interrupts. These interrupts can be prioritized, and are assumed to be signaled to the processor core by means of the FIQ interrupt. Their handlers do not use the facilities supplied by the other two layers. This means that all memory they use must be locked down in the caches. It is possible to use additional code to make access to nonlocked memory possible, but this is not described in this example.

Architectural completion layer

Contains Prefetch Abort, Data Abort and Undefined instruction handlers whose purpose is to give the illusion that the hardware is handling all memory requests and instructions on its own, without requiring software to handle cache misses, and near-exceptional floating-point operations, for example. This illusion is not available to the real-time layer, because the software handlers concerned take a significant number of cycles, and it is not reasonable

to have every memory access to take large numbers of cycles. Instead, the memory concerned has to be locked down.

Non real-time layer

Provides interrupt handlers for low-priority interrupts. These interrupts can also be prioritized, and are assumed to be signaled to the processor core using the IRQ interrupt.

3. The corresponding exception priority structure is as follows, from highest to lowest priority:
 - a. FIQ1 (highest priority FIQ)
 - b. FIQ2
 - c. ...
 - d. FIQm (lowest priority FIQ)
 - e. Data Abort
 - f. Prefetch Abort
 - g. Undefined instruction
 - h. SVC
 - i. IRQ1 (highest priority IRQ)
 - j. IRQ2
 - k. ...
 - l. IRQn (lowest priority IRQ)

The processor core prioritization handles most of the priority structure, but the VIC handles the priorities within each group of interrupts.

————— Note —————

This list reflects the priorities that the handlers are subject to, and differs from the priorities that the exception entry sequences are subject to. The latter priorities are presented in the *ARM Architecture Reference Manual*, and the difference occurs because simultaneous Data Abort and FIQ exceptions result in the sequence:

- a. Data Abort entry sequence executed, updating r14_abt, SPSR_abt, PC, and CPSR.
- b. FIQ entry sequence executed, updating r14_fiq, SPSR_fiq, PC, and CPSR.
- c. FIQ handler executes to completion and returns.
- d. Data Abort handler executes to completion and returns.

4. Stack and register usage is:
 - The FIQ1 interrupt handler has exclusive use of r8_fiq to r12_fiq. In ARMv5, r13_fiq points to a memory area, that is mainly for use by the FIQ1 handler. However, a few words are used during entry for other FIQ handlers. In ARMv6, the FIQ1 interrupt handler has exclusive use of r13_fiq.
 - The Undefined instruction, Prefetch Abort, Data Abort, and non-FIQ1 FIQ handlers use the stack pointed to by r13_abt. This stack is locked down in memory, and therefore of known, limited depth.
 - All IRQ and SVC handlers use the stack pointed to by r13_svc. This stack does not have to be locked down in memory.
 - The stack pointed to by r13_usr is used by the current process. This process can be privileged or unprivileged, and uses System or User mode accordingly.
5. Timings are roughly consistent with ARM10 timings, with the pipeline reload penalty being three cycles. It is assumed that pipeline reloads are combined to execute as quickly as reasonably possible, and in particular that:
 - If an interrupt is detected during an instruction that has set a new value for the PC, after that value has been determined and written to the PC but before the resulting pipeline refill is completed, the pipeline refill is abandoned and the interrupt entry sequence started as soon as possible.
 - Similarly, if an FIQ is detected during an exception entry sequence that does not disable FIQs, after the updates to r14, the SPSR, the CPSR, and the PC but before the pipeline refill has completed, the pipeline refill is abandoned and the FIQ entry sequence started as soon as possible.

FIQs in the example system in ARMv5

In ARMv5, all FIQ interrupts come through the same vector, at address 0x0000001C or 0xFFFF001C. To implement the above system, the code at this vector must get the address of the correct handler from the VIC, branch to it, and transfer to using r13_abt and the Abort mode stack if it is not the FIQ1 handler. The following code does, assuming that r8_fiq holds the address of the VIC:

```
FIQhandler
    LDR    PC, [R8,#HandlerAddress]
...
FIQ1handler
... Include code to process the interrupt ...
    STR    R0, [R8,#AckFinished]
    SUBS   PC, R14, #4
...
FIQ2handler
```

```

        STMIA    R13, {R0-R3}
        MOV     R0, LR
        MRS     R1, SPSR
        ADD     R2, R13, #8
        MRS     R3, CPSR
        BIC     R3, R3, #0x1F
        ORR     R3, R3, #0x1B    ; = Abort mode number
        MSR     CPSR_c, R3
        STMFD   R13!, {R0,R1}
        LDM     R2, {R0,R1}
        STMFD   R13!, {R0,R1}
        LDMDDB  R2, {R0,R1}
        BIC     R3, R3, #0x40    ; = F bit
        MSR     CPSR_c, R3
... FIQs are now re-enabled, with original R2, R3, R14, SPSR on stack
... Include code to stack any more registers required, process the interrupt
... and unstack extra registers
        ADR     R2, #VICaddress
        MRS     R3, CPSR
        ORR     R3, R3, #0x40    ; = F bit
        MSR     CPSR_c, R3
        STR     R0, [R2,#AckFinished]
        LDR     R14, [R13,#12]   ; Original SPSR value
        MSR     SPSR_fsxc, R14
        LDMFD   R13!, {R2,R3,R14}
        ADD     R13, R13, #4
        SUBS    PC, R14, #4
...

```

The major problem with this is the length of time that FIQs are disabled at the start of the lower priority FIQs. The worst-case interrupt latency for the FIQ1 interrupt occurs if a lower priority FIQ2 has fetched its handler address, and is approximately:

- 3 cycles for the pipeline refill after the LDR PC instruction fetches the handler address
- + 24 cycles to get to and execute the MSR instruction that re-enables FIQs
- + 3 cycles to re-enter the FIQ exception
- + 5 cycles for the LDR PC instruction at FIQhandler
- = 35 cycles.

———— **Note** ————

FIQs must be disabled for the final store to acknowledge the end of the handler to the VIC. Otherwise, more badly timed FIQs, each occurring close to the end of the previous handler, can cause unlimited growth of the locked-down stack.

FIQs in the example system in ARMv6

Using the VIC and the new instructions, there is no longer any requirement for everything to go through the single FIQ vector, and the changeover to a different stack occurs much more smoothly. The code is:

```
FIQ1handler
... Include code to process the interrupt ...
    STR    R0, [R8,#AckFinished]
    SUBS   PC, R14, #4
...
FIQ2handler
    SUB     R14, R14, #4
    SRSFD   R13_abt!
    CPSIE   f, #0x1B ; = Abort mode
    STMFD   R13!, {R2,R3}
... FIQs are now re-enabled, with original R2, R3, R14, SPSR on stack
... Include code to stack any more registers required, process the interrupt
... and unstack extra registers
    LDMFD   R13!, {R2,R3}
    ADR     R14, #VICaddress
    CPSID   f
    STR     R0, [R14,#AckFinished]
    RFEFD   R13!
...
```

The worst-case interrupt latency for a FIQ1 now occurs if the FIQ1 occurs during an FIQ2 interrupt entry sequence, after it disables FIQs, and is approximately:

- 3 cycles for the pipeline refill for the FIQ2 exception entry sequence
- + 5 cycles to get to and execute the CPSIE instruction that re-enables FIQs
- + 3 cycles to re-enter the FIQ exception
- = 11 cycles.

Note

In the ARMv5 system, the potential additional interrupt latency caused by a long LDM or STM being in progress when the FIQ is detected was only significant because the memory system could stretch its cycles considerably. Otherwise, it was dwarfed by the number of cycles lost because of FIQs being disabled at the start of a lower-priority interrupt handler. In ARMv6, this is still the case, but it is a lot closer.

Alternatives to the example system

Two alternatives to the design in *FIQs in the example system in ARMv6* on page 2-31 are:

- The first alternative is not to reserve the FIQ registers for the FIQ1 interrupt, but instead either to:
 - Share them out among the various FIQ handlers.
The first restricts the registers available to the FIQ1 handler and adds the software complication of managing a global allocation of FIQ registers to FIQ handlers. Also, because of the shortage of FIQ registers, it is not likely to be very effective if there are many FIQ handlers.
 - Require the FIQ handlers to treat them as normal called-save registers.
The second adds a number of cycles of loading important addresses and variable values into the registers to each FIQ handler before it can do any useful work. That is, it increases the effective FIQ latency by a similar number of cycles.
- The second alternative is to use IRQs for all but the highest priority interrupt, so that there is only one level of FIQ interrupt. This achieves very fast FIQ latency, 5-8 cycles, but at a cost to all the lower-priority interrupts that every exception entry sequence now disables them. You then have the following possibilities:
 - None of the exception handlers in the architectural completion layer re-enable IRQs. In this case, all IRQs suffer from additional possible interrupt latency caused by those handlers, and so effectively are in the non real-time layer. In other words, this results in there only being one priority for interrupts in the real-time layer.
 - All of the exception handlers in the architectural completion layer re-enable IRQs to permit IRQs to have real-time behavior. The problem in this case is that all IRQs can then occur during the processing of an exception in the architectural completion layer, and so they are all effectively in the real-time layer. In other words, this effectively means that there are no interrupts in the non real-time layer.
 - All of the exception handlers in the architectural completion layer re-enable IRQs, but they also use additional VIC facilities to place a lower limit on the priority of IRQs that is taken. This permits IRQs at that priority or higher to be treated as being in the real-time layer, and IRQs at lower priorities to be treated as being in the non real-time layer. The price paid is some additional complexity in the software and in the VIC hardware.

Note

For either of the last two options, the new instructions speed up the IRQ re-enabling and the stack changes that are likely to be required.

2.8.11 Aborts

Aborts are generated by the memory system. An abort can be:

- an internal abort raised by the *Memory Protection Unit* (MPU)
- an external abort being raised from the AXI interfaces, by an AXI error response.

There are two types of abort:

- *Prefetch Abort*
- *Data Abort* on page 2-34.

Note

IRQs are disabled when an abort occurs.

Prefetch Abort

A Prefetch Abort occurs when an unexpected condition occurs during a memory access to fetch an instruction. This is signaled with the Instruction Data as it enters the pipeline Decode stage.

When a Prefetch Abort occurs, the ARM1156T2F-S processor marks the prefetched instruction as invalid, but does not take the exception until the instruction is to be executed. If the instruction is not executed, for example because a branch occurs while it is in the pipeline, the abort does not take place.

To determine the aborting address the abort handler must read the Instruction Fault Address Register (IFAR) in CP15. ARM limited recommends that you do not use the link address in R14 because 32-bit Thumb instructions do not have to be word aligned and can cause an abort on either half-word. This applies even if all of the code in the system does not use Thumb-2 instructions, because the BL and BLX instruction are both 32-bits long.

After dealing with the cause of the abort, the handler executes the following instruction irrespective of the processor operating state:

```
SUBS PC,R14_abt,#4
```

This action restores both the PC and the CPSR, and retries the aborted instruction.

Data Abort

A Data Abort occurs when an unexpected condition occurs during a memory access for data. Data Abort on the ARM1156T2F-S processor can be precise or imprecise. Precise Data Aborts are those generated after performing an instruction side CP15 operation, and all those generated by the MPU:

- alignment faults
- background faults
- permission faults.

Data Aborts that occur because of watchpoints are imprecise in that the processor and system state presented to the abort handler is the processor and system state at the boundary of an instruction shortly after the instruction that caused the watchpoint (but before any following load/store instruction). Because the state that is presented is consistent with an instruction boundary, these aborts are restartable, even though they are imprecise.

Errors that cause externally generated Data Aborts, signaled by **BRESPRW**, **RRESPRW**, or **RESPP**, might be precise or imprecise. Two separate FSR encodings indicate if the external abort is precise or imprecise.

External Data Aborts are precise if:

- all external aborts to loads when the CP15 Register 1 FI bit, bit 21, is set are precise
- all aborts to loads or stores to Strongly Ordered memory are precise
- all aborts to loads to the Program Counter or the CSPR are precise
- all aborts on the load part of a SWP are precise
- all other external aborts are imprecise.

External aborts are supported on cacheable locations. The abort is transmitted to the processor only if a word requested by the processor had an external abort.

Precise Data Aborts

A precise Data Abort is signaled when the abort exception enables the processor and system state presented to the abort handler to be consistent with the processor and system state when the aborting instruction was executed. With precise Data Aborts, the restarting of the processor after the cause of the abort has been rectified is straightforward.

The ARM1156T2F-S processor implements the *base restored Data Abort model*, which differs from the *base updated Data Abort model* implemented by the ARM7TDMI-S.

With the *base restored Data Abort model*, when a Data Abort exception occurs during the execution of a memory access instruction, the base register is always restored by the processor hardware to the value it contained before the instruction was executed. This removes the requirement for the Data Abort handler to unwind any base register update, which might have been specified by the aborted instruction. This simplifies the software Data Abort handler. For more details, see the *ARM Architecture Reference Manual*.

After dealing with the cause of the abort, the handler executes the following return instruction irrespective of the processor operating state at the point of entry:

```
SUBS PC,R14_abt,#8
```

This restores both the PC and the CPSR, and retries the aborted instruction.

Imprecise Data Aborts

An imprecise Data Abort is signaled when the processor and system state presented to the abort handler cannot be guaranteed to be consistent with the processor and system state when the aborting instruction was issued.

2.8.12 Imprecise Data Abort mask in the CPSR/SPSR

An imprecise Data Abort caused, for example, by an External Error on a write that has been held in a Write Buffer, is asynchronous to the execution of the causing instruction and can occur many cycles after the instruction that caused the memory access has retired. For this reason, the imprecise Data Abort can occur at a time that the processor is in Abort mode because of a precise Data Abort, or can have live state in Abort mode, but be handling an interrupt.

To avoid the loss of the Abort mode state (r14 and SPSR_abt) in these cases, which leads to the processor entering an unrecoverable state, the existence of a pending imprecise Data Abort must be held by the system until a time when the Abort mode can safely be entered.

A mask is added into the CPSR to indicate that an imprecise Data Abort can be accepted. This bit is referred to as the A bit. The imprecise Data Abort causes a Data Abort to be taken when imprecise Data Aborts are not masked. When imprecise Data Aborts are masked, then the implementation is responsible for holding the presence of a pending imprecise Data Abort until the mask is cleared and the abort is taken.

The A bit is set automatically on entry into Abort Mode, IRQ, and FIQ Modes, and on Reset.

2.8.13 Supervisor Call instruction

You can use the *Supervisor Call instruction* (SVC) to enter Supervisor mode, usually to request a particular supervisor function.

Note

Previously, the SVC instruction was called SWI, Software Interrupt.

The SVC handler reads the opcode to extract the SVC function number. A SVC handler returns by executing the following instruction, irrespective of the processor operating state:

```
MOVS PC, R14_svc
```

This action restores the PC and CPSR, and returns to the instruction following the SVC.

IRQs are disabled when a Supervisor Call occurs.

The processor modifies the IT execution state bits on exception entry so that the values that the processor writes into the SPSR are correct for the instruction following the SVC. This means that the SVC handler requires no special action to accommodate the IT instruction. For more details on the IT instruction, see the *ARM Architecture Reference Manual*.

2.8.14 Undefined instruction

When an instruction is encountered that neither the ARM1156T2F-S processor, nor any coprocessor in the system, can handle the ARM1156T2F-S processor takes the Undefined instruction trap. Software can use this mechanism to extend the ARM instruction set by emulating undefined coprocessor instructions. Coprocessors can also signal an imprecise exception using the Undefined instruction trap. In this case the exception handler restarts the instruction that caused the Undefined instruction trap. This means that the exception handler must be able to:

- Return after the instruction, if emulating instructions.
If the handler is required to return after the instruction which caused the undefined exception, it must:
 - Advance the IT execution state bits in the SPSR before restoring SPSR to CPSR. This is so that the correct condition codes are applied to the next instruction on return. The pseudo-code for advancing the IT bits is:

```
Cond = SPSR[15:12];
Mask = SPSR[11,10,26,25];
if (Mask != 0) {
    Mask = Mask << 1;
    if (Mask == 0) {
```

- ```

 Cond = 0;
 }
}
SPSR[15:12] = Cond;
SPSR[11,10,26,25] = Mask;

```
- Obtain the instruction that caused the undefined exception and to return correctly after it, exception handlers must also now be aware of the potential for both 16 and 32-bit instructions in Thumb state.  
 After testing the SPSR and determining the instruction was executed in Thumb state, the undefined handler must use the following pseudo-code or equivalent to obtain this information:
 

```

addr = R14_undef - 2
instr = Memory[addr,2]
if (instr >> 11) > 28 { /* 32-bit instruction */
 instr = (instr << 16) | Memory[addr+2,2]
 if (emulating, so return after instruction wanted) {
 R14_undef += 2 // } // }
 }

```

 After this, `instr` holds the instruction (in the range `0x0000-0xE7FF` for a 16-bit instruction, `0xE8000000-0xFFFFFFFF` for a 32-bit instruction), and the exception can be returned from using a `MOVS PC, R14` to return after it.
  - Return before the instruction, if dealing with a coprocessor imprecise exception. For example, a VFP imprecise floating-point exception.  
 After emulating the failed instruction, the trap handler executes the following instruction, irrespective of the processor operating state:
 

```

SUBS PC,R14_und, #2

```

 This action restores the CPSR and returns to the next instruction after the undefined instruction.

IRQs are disabled when an undefined instruction trap occurs. For more details about undefined instructions, see the *ARM Architecture Reference Manual*.

### 2.8.15 Breakpoint instruction (BKPT)

A breakpoint (BKPT) instruction operates as though the instruction causes a Prefetch Abort.

A breakpoint instruction does not cause the ARM1156T2F-S processor to take the Prefetch Abort exception until the instruction reaches the Execute stage of the pipeline. If the instruction is not executed, for example because a branch occurs while it is in the pipeline, the breakpoint does not take place.

After dealing with the breakpoint, the handler executes the following instruction irrespective of the processor operating state:

```

SUBS PC,R14_abt,#4

```

This action restores both the PC and the CPSR, and retries the breakpointed instruction.

**Note**

If the EmbeddedICE-RT logic is configured into Halt debug-mode, a breakpoint instruction causes the ARM1156T2F-S processor to enter Debug state. See *Halting debug-mode debugging* on page 13-47.

2.8.16 Exception vectors

You can configure the location of the exception vector addresses by setting the V bit in CP15 c1 Control Register as shown in Table 2-7.

Table 2-7 Configuration of exception vector address locations

| Value of V bit | Exception vector base location |
|----------------|--------------------------------|
| 0              | 0x00000000                     |
| 1              | 0xFFFF0000                     |

Table 2-8 shows the exception vector addresses and entry conditions for the different exception types.

Table 2-8 Exception vectors

| Exception             | Offset from vector base | Mode on entry | A bit on entry | F bit on entry | I bit on entry |
|-----------------------|-------------------------|---------------|----------------|----------------|----------------|
| Reset                 | 0x00                    | Supervisor    | Disabled       | Disabled       | Disabled       |
| Undefined instruction | 0x04                    | Undefined     | Unchanged      | Unchanged      | Disabled       |
| Supervisor Call       | 0x08                    | Supervisor    | Unchanged      | Unchanged      | Disabled       |
| Abort (prefetch)      | 0x0C                    | Abort         | Disabled       | Unchanged      | Disabled       |
| Abort (data)          | 0x10                    | Abort         | Disabled       | Unchanged      | Disabled       |
| Reserved              | 0x14                    | Reserved      | -              | -              | -              |
| IRQ                   | 0x18                    | IRQ           | Disabled       | Unchanged      | Disabled       |
| FIQ                   | 0x1C                    | FIQ           | Disabled       | Disabled       | Disabled       |

## 2.8.17 Exception priorities

When multiple exceptions arise at the same time, a fixed priority system determines the order that they are handled:

1. Reset (highest priority).
2. Precise Data Abort.
3. FIQ.
4. IRQ.
5. Prefetch Abort.
6. Imprecise Data Aborts.
7. BKPT, undefined instruction, and SVC (lowest priority).

Some exceptions cannot occur together:

- The BKPT, or undefined instruction, and SVC exceptions are mutually exclusive. Each corresponds to a particular, non-overlapping, decoding of the current instruction.
- When FIQs are enabled, and a precise Data Abort occurs at the same time as an FIQ, the ARM1156T2F-S processor enters the Data Abort handler, and proceeds immediately to the FIQ vector.

A normal return from the FIQ causes the Data Abort handler to resume execution. Precise Data Aborts must have higher priority than FIQs to ensure that the transfer error does not escape detection. You must add the time for this exception entry to the worst-case FIQ latency calculations in a system that uses aborts to support virtual memory.

The FIQ handler must not access any memory that can generate a Data Abort, because the initial Data Abort exception condition is lost if this happens.

## 2.9 Acceleration of execution environments

Because the ARMv6 architecture requires Jazelle® software compatibility, three Jazelle registers are implemented in the processor.

Table 2-9 shows the Jazelle register instruction summary and the response to the instructions.

Table 2-9 Jazelle register instruction summary

| Register                   | Instruction                 | Response      |
|----------------------------|-----------------------------|---------------|
| Jazelle ID                 | MRC p14, 7, <Rd>, c0, c0, 0 | Reads as zero |
|                            | MCR p14, 7, <Rd>, c0, c0, 0 | Ignore writes |
| Jazelle main configuration | MRC p14, 7, <Rd>, c2, c0, 0 | Read as zero  |
|                            | MCR p14, 7, <Rd>, c2, c0, 0 | Ignore writes |
| Jazelle OS control         | MRC p14, 7, <Rd>, c1, c0, 0 | Read as zero  |
|                            | MCR p14, 7, <Rd>, c1, c0, 0 | Ignore writes |

———— **Note** ————

- Because no hardware acceleration is present in the processor when the BXJ instruction is used the BX instruction is invoked.
  - If you attempt to set the J bit to 1 the result has Unpredictable behavior.
-

# Chapter 3

## System Control Coprocessor

This chapter describes the purpose of the system control coprocessor, its structure, operation, and how to use it. It contains the following sections:

- *About control coprocessor CP15* on page 3-2
- *System control processor registers* on page 3-11
- *System control coprocessor reference data* on page 3-109.

## 3.1 About control coprocessor CP15

The section gives an overall view of the system control coprocessor. For reference data, see *System control coprocessor reference data* on page 3-109.

The purpose of the system control coprocessor, CP15, is to control and provide status information for the functions implemented in the ARM1156T2F-S processor. The main functions of the system control coprocessor are:

- overall system control and configuration
- optional cache configuration and management
- optional *Tightly-Coupled Memory* (TCM) configuration and management
- optional *Memory Protection Unit* (MPU) configuration and management
- debug accesses to the caches
- system performance monitoring.

The system control coprocessor appears as a set of 32-bit registers that you can write to and read from.

### 3.1.1 System control processor functional groups

The control processor uses these functional groups:

- *System control and configuration* on page 3-5
- *MPU configuration and control* on page 3-6
- *Cache configuration and control* on page 3-7
- *Cache debug and software test access* on page 3-9
- *System performance monitor* on page 3-10.

### 3.1.2 CP15 registers arranged by function

Table 3-1 shows the system functions of the CP15 control registers.

**Table 3-1 CP15 register functions**

| Function                         | Register/operation         | Reference to description                                               |
|----------------------------------|----------------------------|------------------------------------------------------------------------|
| System control and configuration | ID code <sup>a</sup>       | <i>c0</i> , Main ID Register on page 3-18                              |
|                                  | Feature ID                 | <i>c0</i> , Core feature ID registers on page 3-26                     |
|                                  | Control                    | <i>c1</i> , Control Register on page 3-46                              |
|                                  | Auxiliary Control          | <i>c1</i> , Auxiliary Control Register on page 3-50                    |
|                                  | Coprocessor Access Control | <i>c1</i> , Coprocessor Access Control Register on page 3-53           |
|                                  | Process ID                 | <i>c13</i> , Process ID Register on page 3-85                          |
| MPU configuration and control    | MPU Type                   | <i>c0</i> , MPU Type Register on page 3-25                             |
|                                  | Data Fault Status          | <i>c5</i> , Data Fault Status Register on page 3-54                    |
|                                  | Instruction Fault Status   | <i>c5</i> , Instruction Fault Status Register on page 3-56             |
|                                  | Fault Address              | <i>c6</i> , Fault Address Register on page 3-57                        |
|                                  | Watchpoint Fault Address   | <i>c6</i> , Watchpoint Fault Address Register on page 3-57             |
|                                  | Instruction Fault Address  | <i>c6</i> , Instruction Fault Address Register on page 3-58            |
|                                  | MPU Region Base Address    | <i>c6</i> , Memory region programming registers on page 3-59           |
|                                  | MPU Region Size and Enable |                                                                        |
|                                  | MPU Region Access Control  |                                                                        |
| Cache configuration and control  | MPU Region Number Control  |                                                                        |
|                                  | Cache Type                 | <i>c0</i> , Cache Type Register on page 3-20                           |
|                                  | Cache Dirty Status         | <i>c7</i> , Cache Dirty Status Register on page 3-78                   |
|                                  | Cache operations           | <i>c7</i> , Cache Operations Register on page 3-66                     |
|                                  | Data Cache Lockdown        | <i>c9</i> , Data and instruction cache lockdown registers on page 3-79 |
|                                  | Instruction Cache Lockdown |                                                                        |

Table 3-1 CP15 register functions (continued)

| Function                             | Register/operation                       | Reference to description                                                        |

a. Returns device ID code.

3.1.3 System control and configuration

The purpose of the system control and configuration registers is to provide overall management of:

- memory functionality
- interrupt behavior
- exception handling
- program flow prediction
- coprocessor access rights for CP0-CP13.

The system control and configuration registers also provide the processor ID for system debug using context aware breakpoints and use with *Embedded Trace Macrocell* (ETM) where integrated.

The system control and configuration registers consist of one 32-bit read-only register and four 32-bit read/write registers. Figure 3-1 shows the arrangement of registers in this functional group.

Figure 3-1 System control and configuration registers

To use the system control and configuration registers you read or write individual registers that make up the group. For more information, see *Use of the system control coprocessor* on page 3-11.

Some of the functionality depends on how you set external signals at reset.

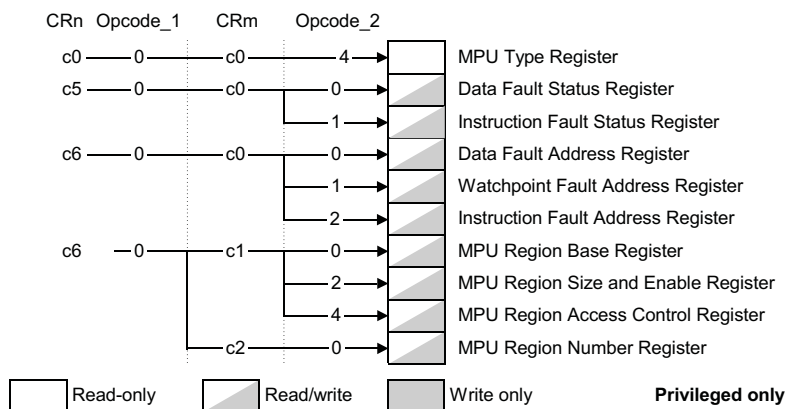

### 3.1.4 MPU configuration and control

The purpose of the MPU control and configuration registers is to:

- control program access to memory
- designate areas of memory as either:
  - uncacheable
  - unbufferable
  - uncacheable and unbufferable
  - cacheable and bufferable.
- detect MPU faults and external aborts.

For more information, see Chapter 5 *Memory Protection Unit*.

The MPU control and configuration registers consist of one 32-bit read-only register, and nine 32-bit read/write registers. Figure 3-2 shows the arrangement of registers in this functional group.

**Figure 3-2 MPU control and configuration registers**

To use the MPU control and configuration registers you read or write individual registers that make up the group. For more information, see *Use of the system control coprocessor* on page 3-11. The MPU is enabled or disabled using the M Bit in the Control Register.

When the processor generates a memory access, the MPU compares the memory address with the programmed memory regions using memory region programming registers:

- If a matching memory region is not found, the MPU signals a memory abort to the processor and the Fault Status and Fault Address Registers are updated.
- If a matching memory region is found the MPU determines the access permission and attributes using the Region Access Control Register. If the access permission and attributes are not valid the MPU signals a memory abort to the processor and the Fault Status and Fault Address Registers are updated.

### 3.1.5 Cache configuration and control

The purpose of the cache control and configuration registers is to:

- provide information on the size and architecture of the instruction and data caches
- control instruction and data cache lockdown
- control cache maintenance operations that include clean and invalidate caches, drain and flush buffers.

For more information, see *Cache organization* on page 7-3.

The cache control and configuration registers consist of one 32-bit write-only register, two 32-bit read-only registers, and six 32-bit read/write registers. Figure 3-3 on page 3-8 shows the arrangement of the registers in this functional group.

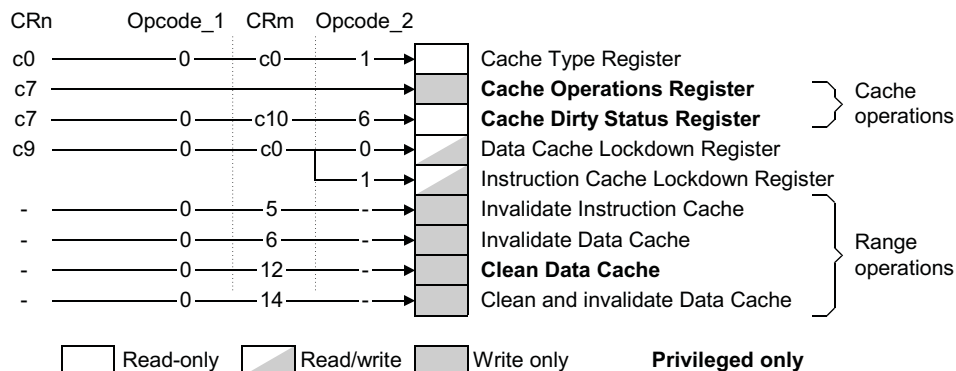

Figure 3-3 Cache control and configuration registers

Range operations can only be performed using an MCRR instruction. To select the required operation you use the <CRm> field. For more information, see *Range operations* on page 3-75.

To use the system control and configuration registers you read or write individual registers that make up the group. For more information, see *Use of the system control coprocessor* on page 3-11.

### 3.1.6 TCM configuration and control

The purpose of the TCM control and configuration registers is to:

- inform the processor about the status of the TCM regions
- define TCM regions.

For more information, see *Tightly-coupled memory* on page 7-12.

The TCM configuration and control registers consist of one 32-bit read-only register, and two 32-bit read/write registers. Figure 3-4 shows the arrangement of registers.

Figure 3-4 TCM configuration and control registers

To use the TCM configuration and control registers you read or write individual registers that make up the group.

It is important when allocating the base address of the TCM to ensure that the same address ranges are not contained in the cache.

### 3.1.7 Cache debug and software test access

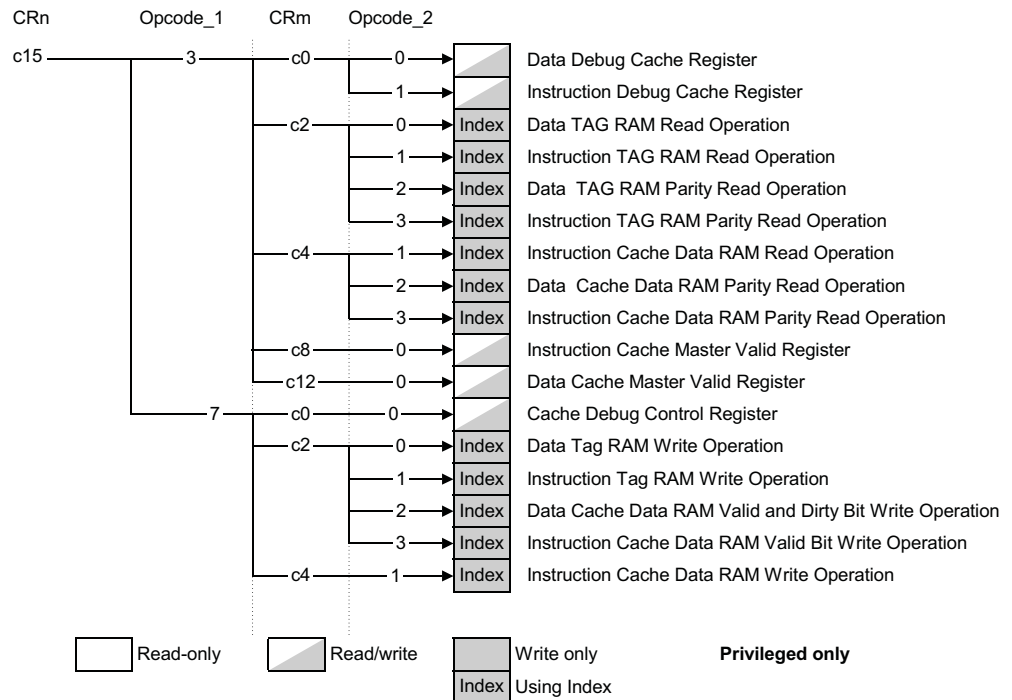

The purpose of the cache debug and software test access registers is to:

- read the contents of instruction cache and data cache.
- hold the value of the Master Valid bits of the instruction and data caches
- control cache debug and software test access.

This method ensures that you can debug an incoherent instruction cache or data cache

For more information, see *Cache debug* on page 7-25.

The cache debug registers consist of 12 32-bit write-only registers, and five 32-bit read/write registers. Figure 3-5 shows the arrangement of registers.

**Figure 3-5** Cache debug and software test access registers

For debug operations, you can disable the cache refill operations, while the caches themselves remain enabled. This enables the debugger to access the system without unsettling the state of the processor.

To use the cache debug and software test access registers you read or write individual registers that make up the group. For more information, see *Use of the system control coprocessor* on page 3-11.

3.1.8 System performance monitor

The purpose of the performance monitor registers is to:

- control the monitoring operation
- monitor events.

The system performance monitor consists of four 32-bit read/write registers. Figure 3-6 shows the arrangement of registers in this functional group.

Figure 3-6 System performance monitor registers

To use the system performance monitor registers you read or write individual registers that make up the group. For more information, see *Use of the system control coprocessor* on page 3-11.

The system performance monitor records system events, such as cache misses, pipeline stalls, and other related features to enable system developers to profile the performance of their systems. It can generate interrupts when the number of events reaches a given value.

## 3.2 System control processor registers

This section gives details of the general method for use of the system control coprocessor and allocation of all the registers in the system control coprocessor. The section presents a summary of the registers and detailed descriptions in register order of CRn, Opcode\_1, CRm, Opcode\_2.

### 3.2.1 Use of the system control coprocessor

This section describes the general method for use of the system control coprocessor using ARM and Thumb-2 MCR/MCRR and MRC instructions.

You can access CP15 registers with:

- ARM MRC and MCR instructions:  
MRC{cond} P15, <Opcode\_1>, <Rd>, <CRn>, <CRm>, <Opcode\_2>  
MRC{cond} P15, <Opcode\_1>, <Rd>, <CRn>, <CRm>, <Opcode\_2>
- ARM MCRR instructions:  
MCRR{cond} P15, <Opcode>, <Rd>, <CRn>, <CRm>
- Thumb-2 MRC and MCR instructions:  
MRC P15, <Opcode\_1>, <Rd>, <CRn>, <CRm>, <Opcode\_2>  
MRC P15, <Opcode\_1>, <Rd>, <CRn>, <CRm>, <Opcode\_2>
- Thumb-2 MCRR instructions  
MCRR P15, <Opcode>, <Rd>, <CRn>, <CRm>

Figure 3-7 shows the bit pattern for the ARM MCR and MRC instructions.

### Figure 3-7 CP15 ARM MRC and MCR bit pattern

Figure 3-8 on page 3-12 shows the bit pattern for the ARM MRCC bit instruction.

**Figure 3-8 CP15 ARM MRCC bit pattern**

Figure 3-9 shows the bit pattern for the Thumb-2 MCR and MRC instructions.

**Figure 3-9 CP15 Thumb-2 MRC and MCR bit pattern**

Figure 3-10 shows the bit pattern for the Thumb-2 MCRR and MRCC instructions.

**Figure 3-10 CP15 Thumb-2 MCRR bit pattern**

The CRn field of MRC and MCR instructions specifies the coprocessor register to access. The CRm field and Opcode\_2 fields specify a particular action when addressing registers. The L bit distinguishes between an ARM and Thumb-2 MRC (L=1) and an ARM and Thumb-2 MCR (L=0).

Instructions CDP, LDC, and STC, together with unprivileged MRC and MCR/MRCC instructions to privileged-only CP15 locations, cause the Undefined instruction trap to be taken.

---

**Note**

---

- Attempting to read from a nonreadable register, or to write to a nonwritable register causes Undefined exceptions.
- The Opcode, Opcode\_1, Opcode\_2, and CRm fields Should Be Zero in all instructions that access CP15, except when the values specified are used to select desired operations. Using other values results in Unpredictable behavior.

---

In all cases, reading from or writing any data values to any CP15 registers, including those fields specified as *Unpredictable* (UNP), *Should Be One* (SBO), or *Should Be Zero* (SBZ), does not cause any physical damage to the chip.

### 3.2.2 Register allocation

The section presents the registers in order of CRn, Opcode\_1, CRm, Opcode\_2.

Table 3-2 shows the allocation and reset values of the registers of the system control coprocessor where:

- CRn is the register number within CP15
- Op1 is the Opcode\_1 value for the register
- CRm is the operational register.

For information on how to access the registers or operations of the system control coprocessor, see *Use of the system control coprocessor* on page 3-11.

**Table 3-2 Register allocation**

| Crn | Op1 | CRm | Op2                    | Register/operation                  | Type                   | Reset value                          | Page       |           |

|     |     |     | 2   | Data Cache Valid RAM and Dirty RAM write | Write-only | Operation   | page 3-99  |
|     |     | c4  | 1   | Instruction Cache Data RAM write         | Write-only | Operation   | page 3-94  |

a. See *c0, Main ID Register* on page 3-18 for the values of bits [23:20] and bits [3:0].

b. The cache type reset value is determined by the size of the caches implemented.

3.2.3 MCRR operations

Table 3-3 shows the allocation of the MCRR operations of the system control coprocessor, respectively. For information on how to access the MCRR operations of the system control coprocessor, see *Use of the system control coprocessor* on page 3-11.

Table 3-3 MCRR operations

| Op1 | CRm | MCRR operation                  | Type       | Reset value | Page      |
|-----|-----|---------------------------------|------------|-------------|-----------|
| 0   | 5   | Invalidate instruction cache    | Write-only | -           | page 3-75 |
| 0   | 6   | Invalidate data cache           | Write-only | -           |           |
| 0   | 12  | Clean data cache                | Write-only | -           |           |
| 0   | 14  | Clean and Invalidate data cache | Write-only | -           |           |

3.2.4 c0, Main ID Register

The purpose of the Main ID Register is to return the device ID code that contains information about the processor.

The Main ID Register is:

- in CP15 c0
- a 32 bit read-only register
- accessible in privileged modes only.

Figure 3-11 shows the arrangement of bits in the register.

Figure 3-11 Main ID Register format

The contents of the Main ID Register depend on the specific implementation. Table 3-4 shows how the bit values correspond with the Main ID Register functions.

Table 3-4 Main ID Register bit functions

| Bits    | Field               | Function                                                                                                                                                                                                                                  |
|---------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:24] | Implementer         | Indicates implementer, ARM Limited:<br>0x41                                                                                                                                                                                               |
| [23:20] | Variant number      | Implementation defined. In ARM implementations this is the major revision number <i>n</i> of the <i>rnpm</i> revision status, see <i>Product revision status</i> on page xxiv:<br>0x0                                                     |
| [19:16] | Architecture        | Indicates that the architecture is given in the feature registers.<br>0xF                                                                                                                                                                 |
| [15:4]  | Primary part number | Indicates part number, ARM1156T2F-S:<br>0xB56                                                                                                                                                                                             |
| [3:0]   | Revision            | Indicates revision. In ARM implementations this is the minor revision number <i>m</i> of the <i>rnpm</i> revision status, see <i>Product revision status</i> on page xxiv. For example:<br>for release r0p0: 0x0<br>for release r0p4: 0x4 |

———— **Note** —————

If an Opcode\_2 value corresponding to an unimplemented or reserved ID register with CRm equal to c0 and Opcode\_1 = 0 is encountered, the system control coprocessor returns the value of the main ID register.

To use the Main ID Register read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c0
- Opcode\_2 set to 0.

For example:

MRC p15, 0, <Rd>, c0, c0, 0 ;Read Main ID Register

For more information on the processor features, see *c0, Core feature ID registers* on page 3-26.

3.2.5 c0, Cache Type Register

The purpose of the Cache Type Register is to provide information about the size and architecture of the cache for the operating system. This enables the operating system to establish how to clean the cache and how to lock it down. Inclusion of this register enables RTOS vendors to produce future-proof versions of their operating systems.

The Cache Type Register is:

- in CP15 c0
- 32-bit read-only
- accessible in privileged modes only.

All ARMv4T and later cached processors contain this register. Figure 3-12 shows the arrangement of bits in the register.

Figure 3-12 Cache Type Register format

Table 3-5 shows how the bit values correspond with the Cache Type Register functions.

Table 3-5 Cache Type Register bit functions

| Bits    | Field  | Function                                                                                                                                                                                       |
|---------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:29] | SBZ    | Should Be Zero                                                                                                                                                                                 |
| [28:25] | Ctype  | Cache type. The processor supports write back cache, Format C cache lockdown, and Register 7 cache cleaning operations. The C type and S bit provide information about the cache architecture. |
| [24]    | S      | Specifies whether the cache is a unified cache or separate instruction and data caches. Always 1 because the ARM1156T2F-S processor has separate instruction and data caches.                  |
| [23:21] | SBZ    | Should Be Zero                                                                                                                                                                                 |
| [20:18] | Dsize  | Data cache size. The Dsize field indicates the data cache size in conjunction with the DM bit. See Table 3-6 on page 3-21.                                                                     |
| [17:15] | Dassoc | Data cache associativity. See Table 3-7 on page 3-22                                                                                                                                           |
| [14]    | DM     | The data multiplier bit. Set to b1 when cache absent. The Dsize field indicates the data cache size in conjunction with the DM bit. See Table 3-6 on page 3-21.                                |
| [13:12] | Dlen   | Data cache line length. Set to data cache line length of 8 words (b10), that is 32 bytes. All other values for Len are reserved. Indicates data cache line length.                             |

Table 3-5 Cache Type Register bit functions (continued)

| Bits   | Field  | Function                                                                                                                                                                    |
|--------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [11:9] | SBZ    | Should Be Zero                                                                                                                                                              |
| [8:6]  | Isize  | Instruction cache size. The Isize field indicates the instruction cache size in conjunction with the IM bit. See Table 3-6.                                                 |
| [5:3]  | Iassoc | The Iassoc field indicates the instruction cache associativity. See Table 3-7 on page 3-22.                                                                                 |
| [2]    | IM     | The instruction multiplier bit. Set to b1 when cache absent. The instruction size field indicates the instruction cache size in conjunction with the IM bit. See Table 3-6. |
| [1:0]  | Ilen   | Instruction cache line length. Set to instruction cache line length of 8 words (b10), that is 32 bytes. All other values for Ilen are reserved.                             |

Table 3-6 shows how the Dsize and Isize fields indicate the size of the instruction cache and data caches respectively.

Table 3-6 Instruction and data cache sizes

| Dsize and Isize field | Size |
|-----------------------|------|
| b001                  | 1KB  |
| b010                  | 2KB  |
| b011                  | 4KB  |
| b100                  | 8KB  |
| b101                  | 16KB |
| b110                  | 32KB |
| b111                  | 64KB |

Table 3-7 shows how the Dassoc and Iassoc fields indicate the associativity of the instruction cache and data caches respectively.

**Table 3-7 Instruction and data cache associativity**

| Dassoc and lassoc field | Associativity |
|-------------------------|---------------|
| b000                    | 1-way         |
| b001                    | 2-way         |
| b010                    | 4-way         |

To use the Cache Type Register read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c0
- Opcode\_2 set to 1.

For example:

MRC p15, 0, <Rd>, c0, c0, 1 ;returns cache details

Table 3-8 shows the Cache Type Register default values for an ARM1156T2F-S processor with 16KB cache size and:

- separate instruction and data caches
- 4-way cache associativity
- cache line length of eight words
- caches use write-back, CP15 c7 for cache cleaning, and Format C for cache lockdown.

**Table 3-8 Cache Type Register default values**

| Bits    | Field  | Value | Behavior      |
|---------|--------|-------|---------------|
| [31:29] | SBZ    | b000  | -             |
| [28:25] | Ctype  | b1110 | -             |
| [24]    | S      | b1    | Harvard cache |
| [23:21] | SBZ    | b000  | -             |
| [20:18] | Dsize  | b101  | 16KB          |
| [17:15] | Dassoc | b010  | 4-way         |

Table 3-8 Cache Type Register default values (continued)

| Bits    | Field  | Value | Behavior                   |
|---------|--------|-------|----------------------------|
| [14]    | DM     | b0    | -                          |
| [13:12] | DLen   | b10   | 8 words per line, 32 bytes |
| [11:9]  | SBZ    | b000  | -                          |
| [8:6]   | Isize  | b101  | 16KB                       |
| [5:3]   | Iassoc | b010  | 4-way                      |
| [2]     | IM     | b0    | -                          |
| [1:0]   | ILen   | b10   | 8 words per line, 32 bytes |

Table 3-9 shows the Cache Type Register default values for ARM1156T2F-S processor with 0KB cache size, and:

- separate instruction and data caches
- 0-way cache associativity
- cache line length of eight words
- caches use write-back, CP15 c7 for cache cleaning, and Format C for cache lockdown.

Table 3-9 Cache Type Register values for zero cache size

| Bits    | Field    |          | Value | Behavior                   |
|---------|----------|----------|-------|----------------------------|
| [31:29] | Reserved |          | b000  | -                          |
| [28:25] | Ctype    |          | b1110 | -                          |
| [24]    | S        |          | b1    | Harvard cache              |
| [23:21] | Dsize    | Reserved | b000  | -                          |
| [20:18] |          | Size     | b000  | 0KB                        |
| [17:15] |          | Assoc    | b000  | 0                          |
| [14]    |          | M        | b1    | Cache absent               |
| [13:12] | Len      |          | b10   | 8 words per line, 32 bytes |

Table 3-9 Cache Type Register values for zero cache size (continued)

| Bits   | Field |          | Value | Behavior                   |
|--------|-------|----------|-------|----------------------------|
| [11:9] | Isize | Reserved | b000  |                            |
| [8:6]  |       | Size     | b000  | 0KB                        |
| [5:3]  |       | Assoc    | b000  | 0                          |
| [2]    |       | M        | b1    | Cache absent               |
| [1:0]  |       | Len      | b10   | 8 words per line, 32 bytes |

3.2.6 c0, TCM Status Register

The purpose of the TCM Status Register is to inform the processor of the number of *Instruction TCMs* (ITCMs) and *Data TCMs* (DTCMs) in the system.

The TCM Status Register is:

- in CP15 c0
- 32-bit read-only,
- accessible in privileged modes only.

Figure 3-13 shows the arrangement of bits in the register.

Figure 3-13 TCM Status Register format

Table 3-10 shows how the bit values correspond with the TCM Status Register functions.

Table 3-10 TCM Status Register bit functions

| Bits    | Field   | Function                                                                                                         |
|---------|---------|------------------------------------------------------------------------------------------------------------------|
| [31:29] | 0       | Always 0.                                                                                                        |
| [28:19] | SBZ/UNP | Should Be Zero or Unpredictable.                                                                                 |
| [18:16] | DTCM    | Specifies the number of DTCM banks implemented. Always set to b001. The ARM1156T2F-S processor has one Data TCM. |

Table 3-10 TCM Status Register bit functions (continued)

| Bits   | Field   | Function                                                                                                                 |
|--------|---------|--------------------------------------------------------------------------------------------------------------------------|
| [15:3] | SBZ/UNP | Should Be Zero or Unpredictable.                                                                                         |
| [2:0]  | ITCM    | Specifies the number of I TCM banks implemented. Always set to b001. The ARM1156T2F-S processor has one Instruction TCM. |

To use the TCM Status Register read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c0
- Opcode\_2 set to 2.

For example:

MRC p15, 0, <Rd>, c0, c0, 2 ;returns TCM status register

3.2.7 c0, MPU Type Register

The purpose of this register is to hold the value for the number of instruction and data memory regions implemented in the processor.

The MPU Type Register is:

- in CP15 c0
- a 32-bit read-only register
- accessible in privileged modes only.

Figure 3-14 shows the arrangement of bits in the MPU Type Register.

Figure 3-14 MPU Type Register format

Table 3-11 shows how the bit values correspond with the MPU Type Register functions.

**Table 3-11 MPU Type Register bit functions**

| Bits    | Field              | Function                                                                                                                     |
|---------|--------------------|------------------------------------------------------------------------------------------------------------------------------|
| [31:24] | SBZ/UNP            | Should Be Zero or Unpredictable.                                                                                             |
| [23:16] | Instruction region | Instruction region. Specifies the number of instruction regions. Always set to b00.                                          |
| [15:8]  | Data region        | Data or unified region. Specifies the number of data memory region. Set to 0x10 if a MPU is present else set to 0x00.        |
| [7:1]   | SBZ/UNP            | Should Be Zero or Unpredictable.                                                                                             |
| [0]     | S                  | Specifies the type of MPU regions in the processor: Always set to b0. The ARM1156T2F-S processor has unified memory regions. |

To use the MPU Type Register read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c0
- Opcode\_2 set to 4.

For example:

```
MRC p15, 0, <Rd>, c0, c0, 4 ;returns MPU details
```

### 3.2.8 c0, Core feature ID registers

The section describes the core feature ID registers:

- *c0, Processor Feature Register 0* on page 3-27
- *c0, Processor Feature Register 1* on page 3-28
- *c0, Debug Feature Register 0* on page 3-29
- *c0, Auxiliary Feature Register 0* on page 3-30
- *c0, Memory Model Feature Register 0* on page 3-31
- *c0, Memory Model Feature Register 1* on page 3-32
- *c0, Memory Model Feature Register 2* on page 3-34
- *c0, Memory Model Feature Register 3* on page 3-36
- *c0, Instruction Set Attributes Register 0* on page 3-37
- *c0, Instruction Set Attributes Register 1* on page 3-39
- *c0, Instruction Set Attributes Register 2* on page 3-40
- *c0, Instruction Set Attributes Register 3* on page 3-42

- *c0, Instruction Set Attributes Register 4* on page 3-44
- *c0, Instruction Set Attributes Register 5* on page 3-45.

**c0, Processor Feature Register 0**

The purpose of the Processor Feature Register 0 is to provide information about the execution state support and programmer’s model for the processor.

Processor Feature Register 0 is:

- in CP15 c0
- a 32-bit read-only register
- accessible in privileged modes only.

Figure 3-15 shows the bit arrangement for Processor Feature Register 0.

**Figure 3-15 Processor Feature Register 0 format**

Table 3-12 shows how the bit values correspond with the Processor Feature Register 0 functions.

**Table 3-12 Processor Feature Register 0 bit functions**

| Bits    | Field  | Function                                                                                                                                                     |
|---------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:16] | -      | Reserved.<br>UNP/SBZ.                                                                                                                                        |
| [15:12] | State3 | Indicates support for Thumb-2™ execution environment.<br>This is set to 0x0, the ARM1156T2F-S processor does not support the Thumb-2™ execution environment. |
| [11:8]  | State2 | Indicates support for Java extension interface.<br>0x1, ARM1156T2F-S processors support Java.                                                                |
| [7:4]   | State1 | Indicates type of Thumb encoding that the processor supports.<br>0x3, ARM1156T2F-S processors support Thumb and Thumb-2.                                     |
| [3:0]   | State0 | Indicates support for 32-bit ARM instruction set.<br>0x1, ARM1156T2F-S processors support 32-bit ARM instructions.                                           |

The values in the Processor Feature Register 0 are implementation defined.

To use the Processor Feature Register 0 read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c1
- Opcode\_2 set to 0.

For example:

MRC p15, 0, <Rd>, c0, c1, 0 Read Processor Feature Register 0

**c0, Processor Feature Register 1**

The purpose of the Processor Feature Register 1 is to provide information about the execution state support and programmer's model for the processor.

Processor Feature Register 1 is:

- in CP15 c0
- a 32-bit read-only register
- accessible in privileged modes only.

Figure 3-16 shows the bit arrangement for Processor Feature Register 1.

**Figure 3-16 Processor Feature Register 1 format**

Table 3-13 shows how the bit values correspond with the Processor Feature Register 1 functions.

**Table 3-13 Processor Feature Register 1 bit functions**

| Bits   | Field              | Function                                                                                                                                                    |
|--------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:8] | -                  | Reserved.<br>UNP/SBZ.                                                                                                                                       |
| [7:4]  | Security extension | Indicates support for Security Extensions Architecture v1.<br>0x0, ARM1156T2F-S processors does not support Security Extensions Architecture v1, TrustZone. |
| [3:0]  | Programmer's model | Indicates support for standard ARMv4 programmer's model.<br>0x1, ARM1156T2F-S processors support the ARMv4 model.                                           |

The values in the Processor Feature Register 1 are implementation defined.

To use the Processor Feature Register 1 read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c1
- Opcode\_2 set to 1.

For example:

MRC p15, 0, <Rd>, c0, c1, 1 ;Read Processor Feature Register 1

**c0, Debug Feature Register 0**

The purpose of the Debug Feature Register 0 is to provide information about the debug system for the processor.

Debug Feature Register 0 is:

- in CP15 c0
- a 32-bit read-only register
- accessible in privileged modes only.

Figure 3-17 on page 3-30 shows the bit arrangement for Debug Feature Register 0.

Figure 3-17 Debug Feature Register 0 format

Table 3-14 shows how the bit values correspond with the Debug Feature Register 0 functions.

Table 3-14 Debug Feature Register 0 bit functions

| Bits    | Field | Function                                                                                                                                                             |
|---------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:12] | -     | Reserved.<br>UNP/SBZ                                                                                                                                                 |
| [11:8]  | -     | Indicates the type of embedded processor debug model that the processor supports.<br>0x0, ARM1156T2F-S processors do not support the memory mapped debug model.      |
| [7:4]   | -     | Indicates the type of Secure debug model that the processor supports.<br>0x0, ARM1156T2F-S processors do not support the v6.1 Secure debug architecture based model. |
| [3:0]   | -     | Indicates the type of applications processor debug model that the processor supports.<br>0x2, ARM1156T2F-S processors support the v6 debug model.                    |

The values in the Debug Feature Register 0 are implementation defined.

To use the Debug Feature Register 0 read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c1
- Opcode\_2 set to 2.

For example:

MRC p15, 0, <Rd>, c0, c1, 2 ;Read Debug Feature Register 0

c0, Auxiliary Feature Register 0

The purpose of the Auxiliary Feature Register 0 is to provide additional information about the features of the processor.

The Auxiliary Feature Register 0 is:

- in CP15 c0

- a 32-bit read-only register
- accessible in privileged modes only.

The contents of the Auxiliary Feature Register 0 are implementation defined. In the ARM1156T2F-S processor, the Auxiliary Feature Register 0 reads as 0x00000000.

To use the Auxiliary Feature Register 0 read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c1
- Opcode\_2 set to 3.

For example:

MRC p15, 0, <Rd>, c0, c1, 3 ;Read Auxiliary Feature Register 0.

**c0, Memory Model Feature Register 0**

The purpose of the Memory Model Feature Register 0 is to indicate what memory and system architectures the ARM1156T2F-S processor supports.

The Memory Model Feature Register 0 is:

- in CP15 c0
- a 32-bit read-only register
- accessible in privileged modes only.

Figure 3-18 shows the bit arrangement for Memory Model Feature Register 0.

|          |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|
| 31       | 28 | 27 | 24 | 23 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 4 | 3 | 0 |
| Reserved |    | -  |    | -  |    | -  |    | -  |    | -  |   | - |   | - |   |

**Figure 3-18 Memory Model Feature Register 0 format**

Table 3-15 on page 3-32 shows how the bit values correspond with the Memory Model Feature Register 0 functions.

Table 3-15 Memory Model Feature Register 0 bit functions

| Bits    | Field | Function                                                                                                                                |
|---------|-------|-----------------------------------------------------------------------------------------------------------------------------------------|
| [31:28] | -     | Reserved.<br>UNP/SBZ.                                                                                                                   |
| [27:24] | -     | Indicates support for FCSE.<br>0x0, ARM1156T2F-S processors do not support FCSE.                                                        |
| [23:20] | -     | Indicates support for the ARMv6 Auxiliary Control Register.<br>0x1, ARM1156T2F-S processors support the Auxiliary Control Register.     |
| [19:16] | -     | Indicates support for TCM and associated DMA.<br>0x2, ARM1156T2F-S processors support ARMv6 TCM but does not support DMA.               |
| [15:12] | -     | Indicates support for cache coherency with DMA agent, shared memory.<br>0x0, ARM1156T2F-S processors do not support this model.         |
| [11:8]  | -     | Indicates support for cache coherency support with CPU agent, shared memory.<br>0x0, ARM1156T2F-S processors do not support this model. |
| [7:4]   | -     | Indicates support for PMSA.<br>0x2, ARM1156T2F-S processors support PMSA                                                                |
| [3:0]   | -     | Indicates support for <i>Virtual Memory System Architecture</i> (VMSA).<br>0x0, ARM1156T2F-S processors does not support VMSA.          |

The values in the Memory Model Feature Register 0 are implementation defined.

To use the Memory Model Feature Register 0 read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c1
- Opcode\_2 set to 4.

For example:

MRC p15, 0, <Rd>, c0, c1, 4 ;Read Memory Model Feature Register 0.

**c0, Memory Model Feature Register 1**

The purpose of the Memory Model Feature Register 1 is to indicate what level one memory operations the ARM1156T2F-S processor supports.

The Memory Model Feature Register 1 is:

- in CP15 c0
- a 32-bit read-only register
- accessible in privileged modes only.

Figure 3-19 shows the bit arrangement for Memory Model Feature Register 1.

|    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |

The values in the Memory Model Feature Register 1 are implementation defined.

To use the Memory Model Feature Register 1 read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c1
- Opcode\_2 set to 5.

For example:

```
MRC p15, 0, <Rd>, c0, c1, 5 ;Read Memory Model Feature Register 1.
```

### **c0, Memory Model Feature Register 2**

The purpose of the Memory Model Feature Register 2 is to indicate what memory barrier and cache range operations the ARM1156T2F-S processor supports. This register also indicates that wait for interrupt stalling is supported by the processor.

The Memory Model Feature Register 2 is:

- in CP15 c0
- a 32-bit read-only register
- accessible in privileged modes only.

Figure 3-20 shows the bit arrangement for Memory Model Feature Register 2.

The values in the Memory Model Feature Register 2 are implementation defined.

To use the Memory Model Feature Register 2 read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c1
- Opcode\_2 set to 6.

For example:

MRC p15, 0, <Rd>, c0, c1, 6 ;Read Memory Model Feature Register 2.

### c0, Memory Model Feature Register 3

The purpose of the Memory Model Feature Register 3 is to indicate what level-2 cache memory operations the ARM1156T2F-S processor supports.

The Memory Model Feature Register 3 is:

- in CP15 c0
- a 32-bit read-only register
- accessible in privileged modes only.

Figure 3-21 shows the bit arrangement for Memory Model Feature Register 3.

### Figure 3-21 Memory Model Feature Register 3 format

Table 3-18 on page 3-37 shows how the bit values correspond with the Memory Model Feature Register 3 functions.

**Table 3-18 Memory Model Feature Register 3 bit functions**

| Bit    | Field | Function                                                                                                                                        |

The values in the Memory Model Feature Register 3 are implementation defined.

To use the Memory Model Feature Register 3 read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c1
- Opcode\_2 set to 7.

For example:

MRC p15, 0, <Rd>, c0, c1, 7 ;Read Memory Model Feature Register 3.

**c0, Instruction Set Attributes Register 0**

The purpose of the Instruction Set Attributes Register 0 is to provide information about the instruction set that the processor supports beyond the basic set.

The Instruction Set Attributes Register 0 is:

- in CP15 c0
- a 32-bit read-only register
- accessible in privileged modes only.

Figure 3-22 on page 3-38 shows the bit arrangement for Instruction Set Attributes Register 0.

The values in the Instruction Set Attributes Register 0 are implementation defined.

To use the Instruction Set Attributes Register 0 read CP15 with:

- Opcode\_1 set to 0

- CRn set to c0
- CRm set to c2
- Opcode\_2 set to 0.

For example:

```
MRC p15, 0, <Rd>, c0, c2, 0 ;Read Instruction Set Attributes Register 0
```

**c0, Instruction Set Attributes Register 1**

The purpose of the Instruction Set Attributes Register 1 is to provide information about the instruction set that the processor supports beyond the basic set.

The Instruction Set Attributes Register 1 is:

- in CP15 c0
- a 32-bit read-only register
- accessible in privileged modes only.

Figure 3-23 shows the bit arrangement for Instruction Set Attributes Register 1.

**Figure 3-23 Instruction Set Attributes Register 1 format**

Table 3-20 shows how the bit values correspond with the Instruction Set Attributes Register 1 functions.

**Table 3-20 Instruction Set Attributes Register 1 bit functions**

| Bit     | Field | Function                                                                                                                                                                                                        |

| [11:8]  | -     | Indicates support for exception 2 instructions.<br>0x1, ARM1156T2F-S processors support SRS, RFE, and CPS.                                                                                                                                             |
| [7:4]   | -     | Indicates support for exception 1 instructions.<br>0x1, ARM1156T2F-S processors support LDM(2), LDM(3) and STM(2).                                                                                                                                     |
| [3:0]   | -     | Indicates support for endianness control instructions.<br>0x1, ARM1156T2F-S processors support SETEND and E bit in PSRs.                                                                                                                               |

The values in the Instruction Set Attributes Register 1 are implementation defined.

To use the Instruction Set Attributes Register 1 read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c2
- Opcode\_2 set to 1.

For example:

MRC p15, 0, <Rd>, c0, c2, 1 ;Read Instruction Set Attributes Register 1

**c0, Instruction Set Attributes Register 2**

The purpose of the Instruction Set Attributes Register 2 is to provide information about the instruction set that the processor supports beyond the basic set.

The Instruction Set Attributes Register 2 is:

- in CP15 c0
- a 32-bit read-only register
- accessible in privileged modes only.

Figure 3-24 on page 3-41 shows the bit arrangement for Instruction Set Attributes Register 2.

Table 3-21 Instruction Set Attributes Register 2 bit functions (continued)

| Bits   | Field | Function                                                                                                                        |
|--------|-------|---------------------------------------------------------------------------------------------------------------------------------|
| [11:8] | -     | Indicates support for multi-access interruptible instructions.<br>0x1, ARM1156T2F-S processors support restartable LDM and STM. |
| [7:4]  | -     | Indicates support for memory hint instructions.<br>0x1, ARM1156T2F-S processors support PLD.                                    |
| [3:0]  | -     | Indicates support for load and store instructions.<br>0x1, ARM1156T2F-S processors support LDRD and STRD.                       |

The values in the Instruction Set Attributes Register 2 are implementation defined.

To use the Instruction Set Attributes Register 2 read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c2
- Opcode\_2 set to 2.

For example:

MRC p15, 0, <Rd>, c0, c2, 2 ;Read Instruction Set Attributes Register 2

c0, Instruction Set Attributes Register 3

The purpose of the Instruction Set Attributes Register 3 is to provide information about the instruction set that the processor supports beyond the basic set.

The Instruction Set Attributes Register 3 is:

- in CP15 c0
- a 32-bit read-only registers
- accessible in privileged modes only.

Figure 3-25 shows the bit arrangement for Instruction Set Attributes Register 3.

Figure 3-25 Instruction Set Attributes Register 3 format

Table 3-22 shows how the bit values correspond with the Instruction Set Attributes Register 3 functions.

**Table 3-22 Instruction Set Attributes Register 3 bit functions**

| Bits    | Field | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

The values in the Instruction Set Attributes Register 3 are implementation defined.

To use the Instruction Set Attributes Register 3 read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c2
- Opcode\_2 set to 3.

For example:

```
MRC p15, 0, <Rd>, c0, c2, 3 ;Read Instruction Set Attributes Register 3
```

**c0, Instruction Set Attributes Register 4**

The purpose of the Instruction Set Attributes Register 4 is to provide information about the instruction set that the processor supports beyond the basic set.

The Instruction Set Attributes Register 4 is:

- in CP15 c0
- a 32-bit read-only register
- accessible in privileged modes only.

Figure 3-26 shows the bit arrangement for Instruction Set Attributes Register 4.

**Figure 3-26 Instruction Set Attributes Register 4 format**

Table 3-23 on page 3-45 shows how the bit values correspond with the Instruction Set Attributes Register 4 functions.

Table 3-23 Instruction Set Attributes Register 4 bit functions

| Bits    | Field | Function                                                                                                                                                                                                                                                                  |

| [3:0]   | -     | Indicates support for Unprivileged instructions.<br>0x2, ARM1156T2F-S processors support LDRBT, LDRT, STRBT, STRT, LDRHT, LDRSBT, LDRSHT, and STRHT.                                                                                                                      |

The values in the Instruction Set Attributes Register 4 are implementation defined.

To use the Instruction Set Attributes Register 4 read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c2
- Opcode\_2 set to 4.

For example:

```
MRC p15, 0, <Rd>, c0, c2, 4 ;Read Instruction Set Attributes Register 4
```

**c0, Instruction Set Attributes Register 5**

The purpose of the Instruction Set Attributes Register 5 is to provide additional information about the properties of the processor.

The Instruction Set Attributes Register 5 is:

- in CP15 c0
- a 32-bit read-only registers

- accessible in privileged modes only.

The contents of the Instruction Set Attributes Register 5 are implementation defined. In the ARM1156T2F-S processor, Instruction Set Attributes Register 5 is read as 0x00000000.

To use the Instruction Set Attributes Register 5 read CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c2
- Opcode\_2 set to 5.

For example:

MRC p15, 0, <Rd>, c0, c2, 5 ;Read Instruction Set Attribute Register 5.

3.2.9 c1, Control Register

The purpose of the Control Register is to provide control and configuration of:

- memory alignment, endianness, protection, and fault behavior
- MPU and cache enables and cache replacement strategy
- interrupts and the behavior of interrupt latency
- the location for exception vectors
- program flow prediction.

You can use the Control Register to enable and disable system configuration options.

The Control Register is:

- in CP15 c1
- a 32-bit register
- accessible in privileged modes only.

Figure 3-27 shows the arrangement of bits in the register.

Figure 3-27 Control Register format

Table 3-24 shows how the bit values correspond with the Control Register controls.

**Table 3-24 Control Register bit functions**

| Bits                                                                                                                                            | Field | Function                                                                                                                                                                                                                                                                                                                                                                                                            |

This bit reads as 0 and ignores writes.                                                                                                                                                                                                                                                                                                                                                             |
| [22]                                                                                                                                            | U     | Enables unaligned data access operations for mixed little-endian and big-endian operation:<br>0 = Unaligned data access support disabled<br>1 = Unaligned data access support enabled.<br>The A bit has priority over the U bit.<br>The reset value of the U bit depends on external signals, see Table 3-25 on page 3-49.                                                                                          |

Table 3-24 Control Register bit functions (continued)

| Bits   | Field | Function                                                                                                                                                                                                                                                                                                          |
|--------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [21]   | FI    | Configures low latency features for fast interrupts.<br>0 = All performance features enabled.<br>1 = Low interrupt latency configuration enabled.                                                                                                                                                                 |
| [20]   | SBZ   | Should Be Zero. This bit reads as 0 and ignores writes.                                                                                                                                                                                                                                                           |
| [19]   | SBZ   | Should Be Zero. This bit reads as 0 and ignores writes.                                                                                                                                                                                                                                                           |
| [18]   | SBO   | Should Be One. This bit reads as 1 and ignore writes.                                                                                                                                                                                                                                                             |
| [17]   | SBZ   | Should Be Zero. This bit reads as 0 and ignores writes.                                                                                                                                                                                                                                                           |
| [16]   | SBO   | Should Be One. This bit reads as 1 and ignore writes.                                                                                                                                                                                                                                                             |
| [15]   | L4    | Determines if the T bit is set for PC load instructions:<br>0 = Loads to PC set the T bit.<br>1 = Loads to PC do not set the T bit, ARMv4 behavior.<br>For more details, see the <i>ARM Architecture Reference Manual</i> .                                                                                       |
| [14]   | RR    | Determines the replacement strategy for the cache:<br>0 = Normal replacement strategy by random replacement<br>1 = Predictable replacement strategy by round-robin replacement.                                                                                                                                   |
| [13]   | V     | Determines the location of exception vectors:<br>0 = Normal exception vectors selected, address range = 0x00000000-0x0000001C<br>1 = High exception vectors selected, address range = 0xFFFF0000-0xFFFF001C.                                                                                                      |
| [12]   | I     | Enable or disable level one instruction cache:<br>0 = disabled<br>1 = enabled.                                                                                                                                                                                                                                    |
| [11]   | Z     | Enables programme flow prediction:<br>0 = Program flow prediction disabled<br>1 = Program flow prediction enabled.                                                                                                                                                                                                |
| [10:8] | SBZ   | Should Be Zero. This bit reads as 0 and ignores writes.                                                                                                                                                                                                                                                           |
| [7]    | B     | Determines operation as little-endian or big-endian memory system and the names of the low four-byte addresses within a 32-bit word:<br>0 = Little-endian memory system<br>1 = Big-endian word-invariant memory system.<br>The reset value of the B bit depends on external signals, see Table 3-25 on page 3-49. |
| [6:3]  | SBO   | Should Be One. This field read as 1 and ignore writes.                                                                                                                                                                                                                                                            |

Table 3-24 Control Register bit functions (continued)

| Bits | Field | Function                                                                                                                                                                                                                           |
|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [2]  | C     | Enables or disables level one data cache:<br>0 = Data cache disabled<br>1 = Data cache enabled.                                                                                                                                    |
| [1]  | A     | Enables strict alignment of data to detect alignment faults in data accesses:<br>0 = Strict alignment fault checking disabled.<br>1 = Strict alignment fault checking enabled.<br>The A bit setting takes priority over the U bit. |
| [0]  | M     | Enables or disables the MPU:<br>0 = MPU disabled<br>1 = MPU enabled.                                                                                                                                                               |

Normally, to set the V bit and the B, EE, and U bits you configure signals at reset.

The V bit depends on **VINITHI** at reset:

- **VINITHI** LOW sets V to 0
- **VINITHI** HIGH sets V to 1.

The B, EE, and U bits depend on how you set **BIGENDINIT** and **UBITINIT** at reset. **CFGBIGEND** makes these signals available.

Table 3-25 shows the values of the B, EE, and U bits that result for the reset values of these signals.

Table 3-25 Resultant B bit, U bit, and EE bit values

| CFGBIGEND at reset |            | EE | U | B |
|--------------------|------------|----|---|---|
| UBITINIT           | BIGENDINIT |    |   |   |
| 0                  | 0          | 0  | 0 | 0 |
| 0                  | 1          | 0  | 0 | 1 |
| 1                  | 0          | 0  | 1 | 0 |
| 1                  | 1          | 1  | 1 | 0 |

These bits in the Control Register exhibit specific behavior:

- |               |                                                                                                                                                                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>A bit</b>  | The A bit setting takes priority over the U bit. The Data Abort trap is taken if strict alignment is enabled and the data access is not aligned to the width of the accessed data item.                                                                                                                             |
| <b>DT bit</b> | Use of this bit is deprecated in the ARM1156T2F-S processor.<br>In ARMv6, the TCM blocks have individual enables that apply to each block. As a result, this bit is now redundant and Should Be One. See <i>c9, Data TCM Region Register</i> on page 3-82 for a description of the ARM1156T2F-S TCM enables.        |
| <b>IT bit</b> | Use of this bit is deprecated in the ARM1156T2F-S processor.<br>In ARMv6, the TCM blocks have individual enables that apply to each block. As a result, this bit is now redundant and Should Be One. See <i>c9, Instruction TCM Region Register</i> on page 3-83 for a description of the ARM1156T2F-S TCM enables. |
| <b>R bit</b>  | This bit is not used in the ARM1156T2F-S processor.                                                                                                                                                                                                                                                                 |
| <b>S bit</b>  | This bit is not used in the ARM1156T2F-S processor.                                                                                                                                                                                                                                                                 |
| <b>W bit</b>  | The ARM1156T2F-S processor does not implement the write buffer enable because all memory writes take place through the Write Buffer.                                                                                                                                                                                |

To use the Control Register it is recommended that you use a read modify write technique. To use the Control Register read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c1
- CRm set to c0
- Opcode\_2 set to 0.

For example:

```
MRC p15, 0, <Rd>, c1, c0, 0 ;Read Control Register configuration data
MCR p15, 0, <Rd>, c1, c0, 0 ;Write Control Register configuration data
```

### 3.2.10 c1, Auxiliary Control Register

The purpose of the Auxiliary Control Register is to control:

- program flow
- fast interrupt control
- cache cleaning.

For more information on how the system control coprocessor operates with caches, see *Cache configuration and control* on page 3-7.

The Auxiliary Control Register is:

- in CP15 c1
- a 32-bit read/write register
- accessible in privileged modes only.

Figure 3-28 shows the bit arrangement of the Auxiliary Control Register.

### Figure 3-28 Auxiliary Control Register format

Table 3-26 shows how the bit values correspond with the Auxiliary Control Register functions.

### Table 3-26 Auxiliary Control Register bit functions

| Bits    | Field           | Function                                                                                                                                                                                                                                                         |
|---------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:10] | -               | Should Be Zero on writes, Unpredictable on reads. Reserved.                                                                                                                                                                                                      |
| [9]     | NS              | Override Shared attribute in Normal, Noncacheable data regions when the MPU is disabled or not present:<br>0 = Shared, Normal, Noncacheable<br>1 = Not Shared, Normal, Noncacheable.                                                                             |
| [8]     | BC <sup>a</sup> | Enables or disables the dynamic branch pattern cache, if program flow prediction is enabled by Z bit, bit 11, of CP15 Register c1 <sup>b</sup> :<br>0 = Dynamic branch predictor pattern cache disabled<br>1 = Dynamic branch predictor pattern cache enabled.   |
| [7]     | BL <sup>a</sup> | Enables or disables the dynamic branch predictor loop cache, if program flow prediction is enabled by Z bit, bit 11, of CP15 Register c1 <sup>b</sup> :<br>0 = Dynamic branch predictor loop cache: disabled<br>1 = Dynamic branch predictor loop cache enabled. |
| [6]     | IR              | Enables or disables instruction cache reload on a parity error if PE, bit 2, is set:<br>0 = Instruction cache reload on a parity error disabled<br>1 = Instruction cache reload on a parity error enabled.                                                       |

**Table 3-26 Auxiliary Control Register bit functions (continued)**

| Bits | Field           | Function                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [5]  | RV              | Enables or disables block transfer cache operations:<br>0 = Block transfer cache operations enabled<br>1 = Block transfer cache operations disabled.                                                                                                                                                                                                                                                                                  |
| [4]  | RA              | Enables or disables clean entire data cache:<br>0 = Clean entire data cache enabled<br>1 = Clean entire data cache disabled.                                                                                                                                                                                                                                                                                                          |
| [3]  | FE              | Enables or disables branch folding within the prefetch unit, if program flow prediction is enabled by Z bit, bit 11, of CP15 Register c1 <sup>b</sup> :<br>0 = Branch Folding is disabled<br>1 = Branch Folding is enabled.                                                                                                                                                                                                           |
| [2]  | PE              | Enables or disables the generation and checking of parity information for the Instruction and Data caches, and the Instruction and Data TCMs:<br>0 = Parity generation disabled. When disabled the processor writes 0 (zero) to parity bits of the RAM. Parity errors ignored by the processor.<br>1 = Parity generation enabled. When enabled Odd parity are written to parity bits of the RAM. Parity errors reported to processor. |
| [1]  | DB              | Enables or disables the use of the Dynamic Predictor, if program flow prediction is enabled by Z bit, bit 11, of CP15 Register <sup>b</sup> :<br>0 = Dynamic Prediction is disabled<br>1 = Dynamic Prediction is enabled.                                                                                                                                                                                                             |
| [0]  | RS <sup>a</sup> | Enables or disables the use of the return stack if program flow prediction is enabled. by Z bit, bit 11, of CP15 Register c1 <sup>b</sup><br>0 = Return stack is disabled<br>1 = Return stack is enabled.                                                                                                                                                                                                                             |

a. The BC, BL, and RS bits are set on reset

b. For more details, see *Enabling/disabling program flow prediction* on page 4-3.

To use the Auxiliary Control Register you must use a read modify write technique.

To access the Auxiliary Control Register read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c1
- CRm set to c0
- Opcode\_2 set to 1.

For example:

```
MRC p15, 0, <Rd>, c1, c0, 1 ;Read Auxiliary Control Register
MCR p15, 0, <Rd>, c1, c0, 1 ;Write Auxiliary Control Register
```

ARM Limited recommends that you use a read modify write technique.

3.2.11 c1, Coprocessor Access Control Register

The purpose of the Coprocessor Access Control Register is to set access rights for the coprocessors CP0-CP13. This register has no effect on access to CP14, the debug control coprocessor, or CP15, the system control coprocessor. This register also provides a means for software to determine if any particular coprocessor, CP0-CP13, exists in the system.

The Coprocessor Access Control Register is:

- in CP15 c1
- a 32-bit read/write register
- accessible in privileged modes only.

Figure 3-29 shows the arrangement of bits in the register.

Figure 3-29 Coprocessor Access Control Register format

Table 3-27 shows how the bit values correspond with the Coprocessor Access Control Register functions. Each pair of bits corresponds to the access rights for each coprocessor.

Table 3-27 Coprocessor Access Control Register bit functions

| Bits    | Field              | Function                                                                                                                                                                                                        |
|---------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:24] | SBZ/UNP            | UNP when read. Write SBZ. Reserved                                                                                                                                                                              |
| -       | cp<n> <sup>a</sup> | Coprocessor access control:<br>b00 = Access denied. Attempts to access the corresponding coprocessor generate an Undefined exception.<br>b01 = Privileged access only.<br>b10 = Reserved.<br>b11 = Full access. |

a. <n> is the coprocessor number between 0 and 13.

To use the Coprocessor Access Control Register read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c1
- CRm set to c0
- Opcode\_2 set to 2.

For example:

MRC p15, 0, <Rd>, c1, c0, 2 ;Read Coprocessor Access Control Register  
MCR p15, 0, <Rd>, c1, c0, 2 ;Write Coprocessor Access Control Register

You must execute an *Instruction Memory Barrier* (IMB) sequence immediately after an update of the Coprocessor Access Control Register, see *Instruction Memory Barrier (IMB) instruction* on page 4-7. You must not attempt to execute any instructions that are affected by the change of access rights between the IMB sequence and the register update.

To determine if any particular coprocessor exists in the system write the access bits for the coprocessor of interest with a value other than b00. If the coprocessor does not exist in the system the access rights remain set to b00.

### 3.2.12 c5, Data Fault Status Register

The purpose of the *Data Fault Status Register* (DFSR) is to hold the source of the last data fault.

The Data Fault Status Register is:

- in CP15 c5
- a 32-bit read/write register
- accessible in privileged modes only.

Figure 3-30 shows the bit arrangement in the DFSR.

**Figure 3-30 DF SR format**

Table 3-28 on page 3-55 shows how the bit values correspond with the DFSR functions

Table 3-28 DFSR bit functions

| Bits         | Field              | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:13, 9:4] | SBZ/UNP            | Should Be Zero or Unpredictable                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| [11]         | RW                 | Indicates what type of access caused the abort:<br>0 = Abort caused by Read<br>1 =Abort caused by Write<br>Aborts on CP15 operations. This bit is set to 1.                                                                                                                                                                                                                                                                                                                             |
| [7:4]        | SBZ/UNP            | Should Be Zero or Unpredictable.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| [12,10, 3:0] | SA, SB, and Status | Indicates the Type of fault generated:<br>b000001 = Alignment<br>b000000 = Background<br>b001101 = Permission<br>b001000 = Precise External Decoder Abort<br>b101000 = Precise External Slave Abort<br>b010110 = Imprecise External Decoder Abort<br>b110110 = Imprecise External Slave Abort<br>b011001 = Precise Parity Error Exception<br>b011000 = Imprecise Parity Error Exception<br>b000010 = Debug Event<br>For more details, see <i>Fault status and address</i> on page 5-25. |

To use the DFSR read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c5
- CRm set to c0
- Opcode\_2 set to 0.

For example:

```
MRC p15, 0, <Rd>, c5, c0, 0 ;Read Data Fault Status Register
MCR p15, 0, <Rd>, c5, c0, 0 ;Write Data Fault Status Register
```

3.2.13 c5, Instruction Fault Status Register

The purpose of the *Instruction Fault Status Register* (IFSR) is to hold the source of the last instruction fault.

The IFSR is:

- in CP15 c5
- a 32-bit read/write register
- accessible in privileged modes only.

Figure 3-31 shows the arrangement of bits in the IFSR.

Figure 3-31 IFSR format

Table 3-29 shows how the bit values correspond with the IFSR functions.

Table 3-29 IFSR bit functions

| Bits             | Field              | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:13, 11, 9:4] | SBZ/UNP            | Should Be Zero or Unpredictable                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| [12,10, 3:0]     | SA, SB, and Status | Indicates the Type of fault generated:<br>b000000 = Background<br>b001101 = Permission<br>b001000 = Precise External Decoder Abort<br>b101000 = Precise External Slave Abort<br>b010110 = Imprecise External Decoder Abort<br>b110110 = Imprecise External Slave Abort<br>b011001 = Precise Parity Error Exception<br>b011000 = Imprecise Parity Error Exception<br>b000010 = Debug Event<br>For more details, see <i>Fault status and address</i> on page 5-25. |

To use the IFSR read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c5

- CRm set to c0
- Opcode\_2 set to 1.

For example:

```
MRC p15, 0, <Rd>, c5, c0, 1 ;Read Instruction Fault Status Register
MCR p15, 0, <Rd>, c5, c0, 1 ;Write Instruction Fault Status Register
```

### 3.2.14 c6, Fault Address Register

The purpose of the *Fault Address Register* (FAR) is to hold the address of the fault when a precise abort occurs.

The FAR is:

- in CP15 c6
- a 32-bit read/write register
- accessible in privileged modes only.

To use the FAR read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c6
- CRm set to c0.
- Opcode\_2 set to 0.

For example:

```
MRC p15, 0, <Rd>, c6, c0, 0 ;Read Fault Address Register
MCR p15, 0, <Rd>, c6, c0, 0 ;Write Fault Address Register
```

A write to c6 with Opcode\_2 set to 0 sets the FAR to the value of the data written. This is useful for a debugger to restore the value of the FAR.

The ARM1156T2F-S processor also updates the FAR on debug exception entry because of watchpoints. This is architecturally Unpredictable. See *Effect of a debug event on CP15 registers* on page 13-31 for more details.

### 3.2.15 c6, Watchpoint Fault Address Register

The purpose of the *Watchpoint Fault Address Register* (WFAR) is to hold the address of the instruction that causes the watchpoint.

The register WFAR is:

- in CP15 c6
- a 32-bit read/write register
- accessible in privileged modes only.

When a watchpoint occurs in:

- ARM state, the WFAR contains the address of the instruction causing it plus 0x8.
- Thumb state, the WFAR contains the address of the instruction causing it plus 0x4.

To use the Watchpoint Fault Address Register read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c6
- Opcode\_2 set to 1.

For example:

```
MRC p15, 0, <Rd>, c0, c6, 1 ;Read Watchpoint Fault Address Register
MCR p15, 0, <Rd>, c0, c6, 1 ;Write Watchpoint Fault Address Register
```

A write to CP15 c0 with Opcode\_2 set to 1 sets the Watchpoint Fault Address Register to the value of the data written. This is useful for a debugger to restore the value of the Watchpoint Fault Address Register. For more information on debugging, see Chapter 13 *Debug*.

A read to CP15 c0 returns the Watchpoint Fault Address Register.

### 3.2.16 c6, Instruction Fault Address Register

The purpose of the *Instruction Fault Address Register* (IFAR) is to hold the address of instruction that causes a prefetch abort.

The IFAR is:

- in CP15 c6
- a 32-bit read/write register
- accessible in privileged modes only.

To use the IFAR read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c6
- CRm set to c0
- Opcode\_2 set to 2.

For example:

```
MRC p15, 0, <Rd>, c6, c0, 2 ;Read Instruction Fault Address Register
MCR p15, 0, <Rd>, c6, c0, 2 ;Write Instruction Fault Address Register
```

A write to c6 with Opcode\_2 set to 0 sets the IFAR to the value of the data written. This is useful for a debugger to restore the value of the FAR.

The ARM1156T2F-S processor also updates the WFAR on debug exception entry because of watchpoints. This is architecturally Unpredictable. See *Effect of a debug event on CP15 registers* on page 13-31 for more details.

### 3.2.17 c6, Memory region programming registers

The purpose of the memory region programming registers is to program the MPU regions.

There is one register that specifies which one of the 16 sets of region registers is to be accessed. Each region has its own register to specify:

- region base address
- region size and enable
- region access control.

---

#### Note

- When the MPU is enabled:
  - the MPU determines the access permissions for all accesses to memory, which includes the TCM. Therefore, you must ensure that the memory regions in the MPU are programmed to cover the complete TCM address space with the appropriate access permissions. You must define at least one of the 16 regions in the MPU.
  - an access to an Undefined area of memory causes a background fault to be generated.
- For the TCM space the processor uses the access permissions but ignores the region attributes from MPU.

The location of the TCM base address is set by CP15 c9. For more details, see *c9, Data TCM Region Register* on page 3-82.

---

## c6, Region Base Address Register

The purpose of the Region Base Address is to describe the base address of a region. The region base address must always align to the region size.

The Region Base Address Register is:

- in CP15 c6
- a 32-bit read/write register
- accessible in privileged modes only.

Figure 3-32 shows the arrangement of bits in the register.

### Figure 3-32 Region Base Address Register format

Table 3-30 shows how the bit values correspond with the Region Base Address Register functions.

### Table 3-30 Region Base Address Register bit functions

| Bits   | Field        | Function                                                    |
|--------|--------------|-------------------------------------------------------------|
| [31:5] | Base address | Physical base address. Defines the base address of a region |
| [4:0]  | SBZ          | Should Be Zero                                              |

To use the Data Region Base Address Register read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c6
- CRm set to c1
- Opcode\_2 set to 0.

For example:

MRC p15, 0, <Rd>, c6, c1, 0 ;Read Data Region Base Address Register  
MCR p15, 0, <Rd>, c6, c1, 0 ;Write Data Region Base Address Register

**Table 3-31 Region Size Register bit functions**

| <b>Bits</b> | <b>Field</b> | <b>Function</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:6]      | SBZ          | Should Be Zero                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

c6, Region Access Control Register

The purpose of the Region Access Control Register is to hold the region attributes and access permissions for a given memory region.

The Region Access Control Register is:

- in CP15 c6
- a 32-bit read/write register
- accessible in privileged modes only.

Figure 3-34 shows the arrangement of bits in the register.

Figure 3-34 Region Access Control Register

Table 3-32 shows how the bit values correspond with the Region Access Control Register functions.

Table 3-32 Region Access Control Register bit functions

| Bits    | Field | Function                                                                                                                                               |
|---------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:13] |       | Reserved.                                                                                                                                              |
| [12]    | XN    | Execute never. Determines if a region of memory is executable <sup>a</sup> :<br>0=All instruction fetches enabled<br>1=No instruction fetches enabled. |
| [11]    | -     | Reserved.                                                                                                                                              |
| [10:8]  | AP    | Access permission. Defines the data access permissions. <sup>b</sup><br>For information on AP bit values, see Table 3-33 on page 3-64.                 |
| [7:6]   | -     | Reserved.                                                                                                                                              |
| [5:3]   | TEX   | Type extension. Defines the type extension attribute. <sup>c</sup><br>For information on TEX bit values, see Table 5-4 on page 5-19.                   |

**Table 3-32 Region Access Control Register bit functions (continued)**

| Bits | Field | Function                                                                                                                                                                                                                           |
|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [2]  | S     | Share. Determines if the memory region is Shared or Non-Shared:<br>0 = Non-Shared. If not present the S bit is assumed to be Non-Shared.<br>1 = Shared.<br>This bit only applies to Normal, not Device or Strongly Ordered memory. |
| [1]  | C     | Cacheable. Determines if memory region type Cacheable:<br>0 = Non-Cacheable<br>1 = Cacheable.                                                                                                                                      |
| [0]  | B     | Bufferable. Determines if memory region type Bufferable:<br>0 = Non-Bufferable<br>1 = Bufferable.                                                                                                                                  |

- a. For more details, see *Instruction access permissions* on page 5-22.
- b. For more details, see *Data access permissions* on page 5-22.
- c. For more details, see *Memory region attributes* on page 5-19.

Table 3-33 shows the AP bits values that determine the permissions for Privileged and User data access.

**Table 3-33 Access data permission bit encoding**

| AP bit values | Privileged permissions | User permissions | Description                                    |
|---------------|------------------------|------------------|------------------------------------------------|
| b000          | No access              | No access        | All accesses generate a permission fault       |
| b001          | Read/write             | No access        | Privileged access only                         |
| b010          | Read/write             | Read-only        | Writes in User mode generate permission faults |
| b011          | Read/write             | Read/write       | Full access                                    |
| b100          | UNP                    | UNP              | Reserved                                       |
| b101          | Read-only              | No access        | Privileged read-only                           |
| b110          | Read-only              | Read-only        | Privileged/User read-only                      |
| b111          | UNP                    | UNP              | Reserved                                       |

To use the Region Access Control Registers read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c6
- CRm set to c1
- Opcode\_2 set to 4.

For example:

MRC p15, 0, <Rd>, c6, c1, 4;Read Region access control Register  
MCR p15, 0, <Rd>, c6, c1, 4;Write Region access control Register

To execute instructions in User and/or Privileged mode:

- the region must have read access as defined by the AP bits
- the XN bit must be set to 0.

### c6, Memory Region Number Register

The memory region registers are multiple registers with one register for each memory region implemented. The value contained in the Memory Region Number Register determines which of the multiple registers is accessed.

The Memory Region Number Register is:

- in CP15 c6
- a 32-bit read/write register
- accessible in privileged modes only.

Figure 3-35 shows the arrangement of bits in the register.

### Figure 3-35 Memory Region Number Register format

Table 3-34 shows how the bit values correspond with the Memory Region Number Register bits.

### Table 3-34 Memory Region Number Register bit functions

| Bits   | Field  | Function                                                                                                                                       |
|--------|--------|------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:4] | -      | Reserved.                                                                                                                                      |
| [3:0]  | Region | Defines the group of registers to be accessed. The number of regions supported is defined by the MPU Type Register in the range b0000 - b1111. |

To use the Memory Region Number Registers read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c6
- CRm set to c1
- Opcode\_2 set to 0.

For example:

```
MRC p15, 0, <Rd>, c6, c2, 0 ;Read Memory Region Number Register
MCR p15, 0, <Rd>, c6, c2, 0 ;Write Memory Region Number Register
```

Writing this register with a value of greater than or equal to the number of regions from the MPU Type Register, along with associated register bank accesses, are Unpredictable.

### 3.2.18 c7, Cache Operations Register

The purpose of the Cache Operations Register is to:

- control these operations:
  - clean and invalidate instruction and data caches, including range operations
  - prefetch instruction cache line
  - flush prefetch buffer
  - flush branch target address cache
  - drain write buffer
- implement the Data Memory Barrier (DMB) function
- implement the Wait For Interrupt clock control function.

#### ———— Note ————

Cache operations also depend on:

- the C, W, I and RR bits, see *c1, Control Register* on page 3-46.
- the RA and RV bits, see *c1, Auxiliary Control Register* on page 3-50.

The Cache Operations Register consists of one 32-bit register that performs 28 functions. Figure 3-36 on page 3-67 shows the arrangement of the 19 functions in this group that operate with the MCR and MRC instructions.

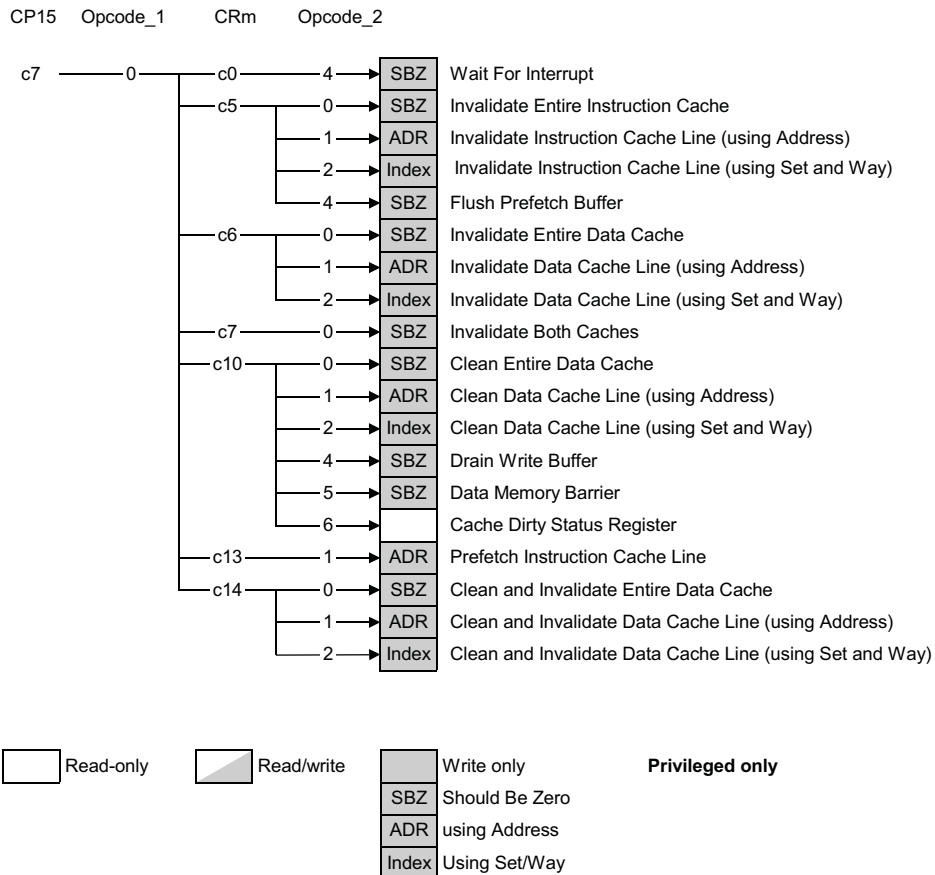

Figure 3-36 Cache operations registers

**Note**

- Writing the Cache Operations Registers with a combination of CRm and Opcode\_2 not listed in *c7, Cache Operations Register* on page 3-66 gives Unpredictable results.
- In the ARM1156T2F-S processor, reading from write-only Cache Operations Registers, causes an Undefined instruction trap.
- If Opcode\_1 = 0, these instructions are applied to the level one cache system. All other Opcode\_1 values are reserved.

- All CP15 c7 operations can only be executed in a privileged mode of operation, except Drain Write Buffer, Flush Prefetch Buffer, and Data Memory Barrier. These can be operated in User mode. Attempting to execute a privileged instruction in User mode results in the Undefined instruction trap being taken.

---

There are three ways to use the Cache Operations Register:

- For the Cache Dirty Status Register, read the Cache Operations Register with the MRC instruction.
- For range operations use the MCRR instruction with the value of CRm to select the required operation.
- For all other operations use the MCR instruction to write to the Cache Operations Register with the combination of CRm and Opcode\_2 to select the required operation

Depending on the operation you require set <Rd> for MCR instructions or <Rd> and <Rn> for MCRR instructions to:

- Physical address
- Way and Set
- Should Be Zero.

### **Invalidate, Clean, and Prefetch operations**

The purposes of the invalidate, clean, and prefetch operations that the Cache Operations Register provide are to:

- Invalidate part or all of the data or instruction caches
- Clean part or all of the data cache
- Clean and Invalidate part or all of the data cache
- Prefetch code into the instruction cache.

The terms used to describe the invalidate, clean, and prefetch operations are as defined in the *Caches and Write Buffers* chapter of the *ARM Architecture Reference Manual*.

When it controls invalidate, clean, and prefetch operations the Cache Operations Register appears as a 32-bit register. There are three possible formats for the data in the register that depend on the specific operation:

- Way and Set format
- Physical Address
- SBZ.

Way and Set format

Figure 3-37 shows the bit arrangement of the Cache Operations Register for use with Way and Set tag for invalidate, clean, and prefetch operations.

Figure 3-37 Cache Operation Register format for Way and Set

Table 3-35 shows how the bit values correspond with the Cache Operation functions for Way and Set operations.

Table 3-35 Cache Operations Register bit functions for Way and Set

| Bits     | Field   | Function                                                                                                                                           |
|----------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:30]  | Way     | Sets the Way to operate on. Table 3-37 on page 3-70 shows the maximum Ways that can be selected for a particular cache size, and the bit settings. |
| [29:S+5] | SBZ/UNP | UNP on reads, SBZ on writes.                                                                                                                       |
| [S+4:5]  | Set     | Set number. Selects the cache line to operate on.                                                                                                  |
| [4:1]    | SBZ     | Should Be Zero                                                                                                                                     |
| [0]      | 0       | For the ARM1156T2F-S this is always 0.                                                                                                             |

Table 3-36 Cache size and Way associativity

| Cache size | Way           | Way bit settings   |
|------------|---------------|--------------------|
| 1KB        | 0             | 00                 |
| 2KB        | 0 and 1       | 00 and 10          |
| ≥4KB       | 0, 1 2, and 3 | 00, 01, 10, and 11 |

The value of S in Table 3-35 on page 3-69 depends on the cache size. Table 3-37 shows the relationship of cache sizes and S.

Table 3-37 Cache size and S parameter dependency

| Cache size       | S |
|------------------|---|
| 1KB, 2KB, or 4KB | 5 |
| 8KB              | 6 |
| 16KB             | 7 |
| 32KB             | 8 |
| 64KB             | 9 |

The value of S is given by:

$$S = \log_2 \left( \frac{\text{cache size}}{\text{Associativity} \times \text{line length in bytes}} \right)$$

See *c0, Cache Type Register* on page 3-20 for more information on instruction and data cache size.

———— **Note** ————

If the data is stated to be Set/ Way format (see Figure 3-37 on page 3-69), it identifies the cache line that the operation applies to by specifying which cache Set it belongs to and what its Way is within the Set. The Way corresponds to the number of the cache way, and the Set number corresponds to the line number within a cache way.

**Address format**

Figure 3-38 shows the bit arrangement of the Cache Operations Register for use with the address for invalidate, clean, and prefetch operations.

Figure 3-38 Cache Operation Register format for the address

Table 3-38 shows how the bit values correspond with the Cache Operation functions for Way and Set tag operations.

**Table 3-38 Cache Operations Register bit functions for address**

| Bits   | Field   | Function                                                                                       |
|--------|---------|------------------------------------------------------------------------------------------------|
| [31:5] | Address | Holds the physical address of the cache line for the invalidate, clean, or prefetch operation. |
| [4:0]  | Ignored | -                                                                                              |

**Note**

If the data is stated to be an address, it does not have to be cache line aligned. This address is looked up in the cache for the particular operation. Invalidation and cleaning operations have no effect if they miss in the cache.

- You can perform invalidate, clean, and prefetch operations on:
- single cache lines
  - entire caches
  - address ranges in cache, but not on prefetch address ranges.

**Note**

- Clean, invalidate, and clean and invalidate operations apply regardless of the lock applied to entries.
- A small number of CP15 c7 operations can be executed by code while in User mode. Attempting to execute a privileged operation in User mode using CP15 c7 results in an Undefined instruction trap being taken.

To determine if the cache is dirty use the Cache Dirty Status operation, see *c7, Cache Dirty Status Register* on page 3-78.

**Single cache lines**

- There are two ways to perform invalidate or clean operations on cache lines:
- By use of Set/Way format
  - By use of address.

Table 3-39 shows the instructions and operations that you can use for single cache lines.

**Table 3-39 Cache Operations Register functions for single lines**

| Instruction                  | Data    | Function                                               |
|------------------------------|---------|--------------------------------------------------------|
| MCR p15, 0, <Rd>, c7, c5, 1  | Address | Invalidate Instruction Cache Line (using address).     |
| MCR p15, 0, <Rd>, c7, c5, 2  | Set/Way | Invalidate Instruction Cache Line (using Set/ Way).    |
| MCR p15, 0, <Rd>, c7, c6, 1  | Address | Invalidate Data Cache Line (using address).            |
| MCR p15, 0, <Rd>, c7, c6, 2  | Set/Way | Invalidate Data Cache Line (using Set/ Way).           |
| MCR p15, 0, <Rd>, c7, c10, 1 | Address | Clean Data Cache Line (using address).                 |
| MCR p15, 0, <Rd>, c7, c10, 2 | Set/Way | Clean Data Cache Line (using Set/ Way).                |
| MCR p15, 0, <Rd>, c7, c13, 1 | Address | Prefetch Instruction Cache Line.                       |
| MCR p15, 0, <Rd>, c7, c14, 1 | Address | Clean and Invalidate Data Cache Line (using address).  |
| MCR p15, 0, <Rd>, c7, c14, 2 | Set/Way | Clean and Invalidate Data Cache Line (using Set/ Way). |

Example 3-1 shows how to use Clean and Invalidate Data Cache Line with Way and Set to clean and invalidate one whole cache way, in this example, way 3. The example works with any cache size because it reads the cache size from the Cache Type Register.

**Example 3-1 Clean and Invalidate Data Cache Line with Way and Set**

|            |     |                   |                           |
|------------|-----|-------------------|---------------------------|
| index_loop | MRC | p15,0,r0,c0,c0,1  | ;Read cache type reg      |
|            | AND | r0,r0,#0x1C0000   | ;Extract D cache size     |
|            | MOV | r0,r0, LSR #18    | ;Move to bottom bits      |
|            | ADD | r0,r0,#7          | ;Get Way loop max         |
|            | MOV | r1,#3:SHL:30      | ;Set up Set = 3           |
|            | MOV | r2,#0             | ;Set up Way counter       |
|            | MOV | r3,#1             |                           |
|            | MOV | r3,r3, LSL r0     | ;Set up Way loop max      |
|            | ORR | r4,r2,r1          | ;Way and Set format       |
|            | MCR | p15,0,r4,c7,c14,2 | ;Clean&inval D cache line |
|            | ADD | r2,r2,#1:SHL:5    | ;IncrementWay             |
|            | CMP | r2,r3             | ;Done all index values?   |
|            | BNE | index_loop        | ;Loop until done          |
|            |     |                   |                           |

Entire cache

Table 3-40 shows the instructions and operations that you can use to clean and invalidate the instruction cache, data cache, or both instruction cache and data cache.

Table 3-40 Cache Operations Register functions for entire cache

| Instruction                  | Data | Function                               |
|------------------------------|------|----------------------------------------|
| MCR p15, 0, <Rd>, c7, c5, 0  | SBZ  | Invalidate Entire Instruction Cache    |
| MCR p15, 0, <Rd>, c7, c6, 0  | SBZ  | Invalidate Entire Data Cache.          |
| MCR p15, 0, <Rd>, c7, c7, 0  | SBZ  | Invalidate Both Caches                 |
| MCR p15, 0, <Rd>, c7, c10, 0 | SBZ  | Clean Entire Data Cache                |
| MCR p15, 0, <Rd>, c7, c14, 0 | SBZ  | Clean and Invalidate Entire Data Cache |

CP15 c7 specifies operations for cleaning the entire data cache, and also for performing a clean and invalidate of the entire data cache. These are blocking operations that can be interrupted. If they are interrupted, the r14 value that is captured on the interrupt is the address of the instruction that launched the cache clean operation + 4. This enables the standard return mechanism for interrupts to restart the operation.

If it is essential that the cache is clean, or clean and invalid, for a particular operation, the sequence of instructions for cleaning, or cleaning and invalidating, the cache for that operation must handle the arrival of an interrupt at any time in which interrupts are not disabled. This is because interrupts can write to a previously clean cache. For this reason, the Cache Dirty Status Register indicates if the cache has been written to since the last clean of the cache was started, see *c7, Cache Dirty Status Register* on page 3-78. You can interrogate the Cache Dirty Status Register to determine if the cache is clean, and if this is done while interrupts are disabled, the following operations can rely on having a clean cache.

The following sequence shows this approach:

```
Loop1 MOV R1, #0
 MCR CP15, 0, R1, C7, C10, 0 ;Clean (or Clean &
 ;Invalidate) Cache

 MRS R2, CPSR
 CPSID iaf ;Disable interrupts
 MRC CP15, 0, R1, C7, C10, 6 ;Read Cache Dirty Status
 ;Register
```

```

 ANDS R1, R1, #01 ;Check if it is clean
 BEQ UseClean
 MSR CPSR, R2 ;Re-enable interrupts
 B Loop1 ;- clean the cache again
UseClean Do_Clean_Operations ;Perform whatever
 ;operation relies on
 ;the cache being
 ;clean/invalid.
 ;To reduce impact on
 ;interrupt latency,
 ;this sequence should be
 ;short
 MSR CPSR, R2 ;Re-enable interrupts
```

The long cache clean operation is performed with interrupts enabled throughout this routine.

For more information on the Cache Dirty Status Register, see *c7, Cache Dirty Status Register* on page 3-78.

Flush operations

Table 3-41 shows the flush operations and instructions available through the Cache Operations Register.

Table 3-41 Cache Operations Register Flush functions

| Instruction                 | Data | Function                             |
|-----------------------------|------|--------------------------------------|
| MCR p15, 0, <Rd>, c7, c5, 0 | SBZ  | Flush entire instruction cache.      |
| MCR p15, 0, <Rd>, c7, c5, 4 | SBZ  | Flush Prefetch Buffer <sup>a</sup> . |
| MCR p15, 0, <Rd>, c7, c7, 0 | SBZ  | Flush both caches.                   |

a. These operations are accessible in both User and Privileged modes of operation. All other operations are only accessible in privileged modes of operation.

Flushing the instruction prefetch buffer has the effect that all instructions occurring in program order after this instruction are fetched from the memory system after the execution of this instruction, including the level one cache or TCM. This operation is useful for ensuring the correct execution of self-modifying code. See *Explicit memory barriers* on page 5-17.

Range operations

The purpose of the range operations is to clean and invalidate areas of instruction or data cache using address ranges. You can only perform these operations using an MCRR instruction, and all other operations to these register are ignored.

Table 3-42 shows the supported block operations.

Table 3-42 Exception behavior to range operations

| Operation                  | Transfer type | Data type           | Mode               | Exception behavior |
|----------------------------|---------------|---------------------|--------------------|--------------------|
| Clean Range                | Blocking      | Data                | User or privileged | Data Abort         |
| Clean and Invalidate Range | Blocking      | Data only           | Privileged         | Data Abort         |
| Invalidate Range           | Blocking      | Instruction or data | Privileged         | Data Abort         |

Each of the range operations is started using an MCRR operation. Table 3-43 shows the range operations and the instructions you can use.

Table 3-43 Cache Operations Register functions for address ranges

| Instruction                                     | Data             | Operation                             |
|-------------------------------------------------|------------------|---------------------------------------|
| MCRR p15, 0, <End Address>, <Start Address>, 5  | Physical address | Invalidate Instruction Cache Range    |
| MCRR p15, 0, <End Address>, <Start Address>, 6  | Physical address | Invalidate Data Cache Range           |
| MCRR p15, 0, <End Address>, <Start Address>, 12 | Physical address | Clean Data Cache Range <sup>a</sup>   |
| MCRR p15, 0, <End Address>, <Start Address>, 14 | Physical address | Clean and Invalidate Data Cache Range |

a. These operations are accessible in both User and Privileged modes of operation. All other operations listed here are only accessible in privileged modes of operation.

Each instruction specifies two registers:

- <Start Address> register specifies the Block Start Address
- <End Address> specifies the Block End Address.

Figure 3-38 on page 3-70 shows the address format for the <Start Address> and <End Address> registers.

Because the least significant address bits [4:0] are ignored, the transfer automatically adjusts to a line length multiple spanning the programmed addresses.

The value of the <Start Address> register is the first address of the block transfer. It uses the address bits [31:5]. The value of the <End Address> register is the address where the block transfer stops. This address is at the start of the line containing the last address to be handled by the block transfer. It uses the address bits [31:5].

All block operations are performed on the cache lines that include the range of addresses between the Block Start Address and Block End Address inclusive.

If the Block Start Address is greater than the Block End Address the effect is architecturally Unpredictable. The ARM1156T2F-S processor does not perform cache operations in this case.

All block transfers are interruptible. When block transfers are interrupted, the r14 value that is captured is the address of the instruction that launched the block operation + 4. This enables the standard return mechanism for interrupts to restart the operation.

Each of the range operations operates between cache lines containing the <Start Address> and the <End Address>, inclusive of <Start Address> and <End Address>.

**Data Memory Barrier operation**

The purpose of the Data Memory Barrier operation is to ensure that all outstanding explicit memory transactions complete before any following explicit memory transactions begin. This ensures that data in memory is up to date before any memory transaction that depends on it.

The Data Memory Barrier operation is:

- in CP15 c7
- a 32-bit write only operation
- accessible in User and Privileged mode.

Table 3-44 shows the results of attempted access for each mode.

**Table 3-44 Results of access to the Data Memory Barrier operation**

| Read                | Write |
|---------------------|-------|
| Undefined exception | Data  |

To use the Data Memory Barrier operation write CP15 with <Rd> set SBZ and:

- Opcode\_1 set to 0
- CRn set to c7
- CRm set to c10
- Opcode\_2 set to 5.

For example:

MCR p15, 0, <Rd>, c7, c10, 5; Write Data Memory Barrier Register.

For more information, see *Explicit memory barriers* on page 5-17.

### Drain Write Buffer operation

The purpose of the Drain Write Buffer operation is to ensure that all explicit memory transactions that occur in program order before this instruction are completed.

The Drain Write Buffer operation is:

- in CP15 c7
- 32-bit write only
- accessible in both User and Privileged modes.

To use the Drain Write Buffer operation write CP15 with <Rd> set SBZ and:

- Opcode\_1 set to 0
- CRn set to c7
- CRm set to c10
- Opcode\_2 set to 4.

For example:

MCR p15, 0, <Rd>, c7, c10, 4; Write Drain Write Buffer.

For more information, see *Explicit memory barriers* on page 5-17.

#### ————— **Note** —————

The W bit that normally enables the Write Buffer is not implemented in the ARM1156T2F-S processor, see *c1, Control Register* on page 3-46.

This instruction acts as an explicit memory barrier. This instruction completes when all explicit memory transactions occurring in program order before this instruction are completed. No instructions occurring in program order after this instruction are executed until this instruction completes. Therefore, no explicit memory transactions occurring in program order after this instruction are started until this instruction completes. See *Explicit memory barriers* on page 5-17.

It can be used instead of Strongly Ordered memory when the timing of specific stores to the memory system has to be controlled. For example, when a store to an interrupt acknowledge location must be completed before interrupts are enabled.

Drain Write Buffer can be executed in both privileged and User modes of operation.

Wait For Interrupt operation

The purpose of the Wait For Interrupt operation is to put the processor in to a low power state.

The Wait For Interrupt Register is:

- in CP15 c7
- 32-bit write only
- accessible only in privileged modes.

To use the Wait For Interrupt operation write CP15 with <Rd> set SBZ and:

- Opcode\_1 set to 0
- CRn set to c7
- CRm set to c0
- Opcode\_2 set to 4.

For example:

```
MCR p15, 0, <Rd>, c7, c0, 4; Wait For Interrupt.
```

This puts the processor into a low-power state and stops it executing more instructions until an interrupt, or debug request occurs, regardless of whether the interrupts are disabled by the masks in the CPSR. When an interrupt does occur, the MCR instruction completes and the IRQ or FIQ handler is entered as normal. The return link in r14\_irq or r14\_fiq contains the address of the MCR instruction plus 8, so that the normal instruction used for interrupt return (SUBS PC,R14,#4) returns to the instruction following the MCR.

3.2.19 c7, Cache Dirty Status Register

The purpose of the Cache Dirty Status Register is to indicate when the cache is dirty.

The Cache Dirty Status Register is:

- in CP15 c7
- 32-bit read-only
- accessible in privileged mode only.

Figure 3-39 shows the arrangement of bits in the register.

Figure 3-39 Cache Dirty Status Register format

The C bit indicates if the cache is dirty:

**C = 0** No write has hit the cache since the last cache clean, clean and invalidate, or invalidate all, or reset operation. The cache is clean.

**C = 1**      The cache might contain dirty data.

To use the Cache Dirty Status Register read CP15 with:

- Opcode\_1 set to 0
- CRn set to c7
- CRm set to c10
- Opcode\_2 set to 6.

For example:

MRC p15, 0, <Rd>, c7, c10, 6; Read Cache Dirty Status Register.

### 3.2.20 c9, Data and instruction cache lockdown registers

The purpose of the data and instruction cache lockdown registers is to provide a means to lockdown the caches and therefore provide some control over pollution that applications might cause. With these registers you can lockdown each cache way independently.

There are two cache lockdown registers:

- one Data Cache Lockdown Register
- one Instruction Cache Lockdown Register.

The Cache Lockdown Registers are:

- in CP15 c9
- 32-bit read/write register
- only accessible in privileged modes.

Figure 3-40 shows the bit arrangement of the Cache Lockdown Registers.

### Figure 3-40 Instruction and Data Cache Lockdown Registers format

Table 3-45 shows how the bit values correspond with the Cache Lockdown Registers functions.

**Table 3-45 Instruction and Data Cache Lockdown Registers bit functions**

| Bits   | Field                    | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:4] | SBO                      | UNP on reads, SBO on writes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| [3:0]  | L bit for each cache way | <p>Locks each cache way individually. The L bits for cache ways 3 to 0 are bits [3:0] respectively. On a line fill to the cache, data is allocated to unlocked cache ways as determined by the standard replacement algorithm. Data is not allocated to locked cache ways. If a cache way is not implemented, then the L bit for that way is hardwired to 1, and writes to that bit are ignored.</p> <p>0 = This cache way is not locked. Allocation to this cache way is determined by the standard replacement algorithm. This is the reset state.</p> <p>1 = This cache way is locked. No allocation is performed to this cache way.</p> |

The data Cache Lockdown Register only supports the Format C method of lockdown. This method is a cache way based scheme that gives a traditional lockdown function to lock critical ways in the cache. For more information on cache lockdown methods, see the *ARM Architecture Reference Manual*.

A locking bit for each cache way determines if the normal cache allocation mechanisms, Random or Round-Robin, can access that cache way. For more information on the RR bit that controls the selection of Random or Round-Robin cache policy, see *c1, Control Register* on page 3-46.

ARM1156T2F-S processors have 4, 2 or 1 way set-associativity cache. With all ways locked, the ARM1156T2F-S processor behaves as if way 0 is locked and all other ways are unlocked.

To use the Instruction and Data Cache Lockdown Registers read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c9
- CRm set to c0
- Opcode\_2 set to:
  - 0, for data cache
  - 1, for instruction cache.

For example:

```
MRC p15, 0, <Rd>, c9, c0, 0 ;Read Data Cache Lockdown Register
MCR p15, 0, <Rd>, c9, c0, 0 ;Write Data Cache Lockdown Register
MRC p15, 0, <Rd>, c9, c0, 1 ;Read Instruction Cache Lockdown Register
MCR p15, 0, <Rd>, c9, c0, 1 ;Write Instruction Cache Lockdown Register
```

The system must only change a Cache Lockdown Register when it is certain that all outstanding accesses that might cause a cache line fill are complete. For this reason, the processor must execute a Drain Write Buffer instruction before the Cache Lockdown Register changes, see *Drain Write Buffer operation* on page 3-77.

The following procedure for lock down into a data or instruction cache way *i*, with *N* cache ways, using Format C, ensures that only the target cache way *i* is locked down.

This is the architecturally defined method for locking data into caches:

1. Ensure that no processor exceptions can occur during the execution of this procedure, by disabling interrupts. If this is not possible, all code and data used by any exception handlers that can be called must meet the conditions specified in step 2.
2. Ensure that all data used by the following code, apart from the data that is to be locked down, is either:
  - in an uncacheable area of memory, including the TCM
  - in an already locked cache way.
3. Ensure that the data to be locked down is in a Cacheable area of memory.
4. Ensure that the data to be locked down is not already in the cache, using cache Clean and/or Invalidate instructions as appropriate. See *Invalidate, Clean, and Prefetch operations* on page 3-68.
5. Enable allocation to the target cache way by writing to CP15 c9, with the CRm field set to 0, setting L equal to 0 for bit *i* and L equal to 1 for all other ways.
6. Ensure that the memory cache line is loaded into the cache by using an LDR instruction to load a word from the memory cache line, for each of the cache lines to be locked down in cache way *i*.

If an instruction cache is to be locked down, use the prefetch instruction cache line operation to fetch the memory cache line into the cache. Write CP15 with CRn set to c7, CRm set to c13, and opcode\_2 set to 1.

7. Write to CP15 c9, CRm set to c0, setting L to 1 for bit *i* and restore all the other bits to the values they had before this routine was started.

3.2.21 c9, Data TCM Region Register

The purpose of the Data TCM Region Register is to hold the base address and size of the Data TCM. It also determines if Data TCM is enabled.

The Data TCM Region Register is:

- in CP15 c9
- 32-bit read/write register,
- accessible in privileged modes only.

Figure 3-42 on page 3-83 shows the arrangement of bits in the register.

Figure 3-41 Data TCM Region Register

Table 3-46 shows how the bit values correspond with the Data TCM Region Register.

Table 3-46 Data TCM Region Register bit functions

| Bits    | Field        | Value                                                                                                                               | Function                                                                                                                                                                                                                            |
|---------|--------------|-------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:12] | Base address | Physical base address                                                                                                               | Base address. Defines the physical base address of the Data TCM. The base address must be aligned to the size of the Data TCM. Any bits in the range $[(\log_2(\text{RAMSize})-1):12]$ are ignored. The base address is 0 at Reset. |
| [11:7]  | -            | UNP on reads, SBZ on writes                                                                                                         | -                                                                                                                                                                                                                                   |
| [6:2]   | Size         | b00000 = 0KB<br>b00011 = 4KB<br>b00100 = 8KB<br>b00101 = 16KB<br>b00110 = 32KB<br>b00111 = 64KB<br>b01000 = 128KB<br>b0100 = 256KB. | Size. Defines the size of the Data TCM on reads. On writes this field is ignored. See <i>Tightly-coupled memory</i> on page 7-12.                                                                                                   |
| [1]     | -            | SBZ                                                                                                                                 | Should Be Zero                                                                                                                                                                                                                      |
| [0]     | En           | 0 = disabled<br>1 = enabled                                                                                                         | Enable. Enables or disables the Data TCM.                                                                                                                                                                                           |

To use the Data TCM Region Register read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c9
- CRm set to c1
- Opcode\_2 set to 0.

For example:

MRC p15, 0, <Rd>, c9, c1, 0; Read Data TCM Region Register  
MCR p15, 0, <Rd>, c9, c1, 0; Write Data TCM Region Register

3.2.22 c9, Instruction TCM Region Register

The purpose of the Instruction TCM Region Register is to hold the base address and size of the Instruction TCM. It also determines if Instruction TCM is enabled.

The Instruction TCM Region Register is:

- in CP15 c9
- 32-bit read/write register,
- accessible in privileged modes only.

Figure 3-42 shows the arrangement of bits in the register.

Figure 3-42 Instruction TCM Region Register format

Table 3-47 on page 3-84 shows how the bit values correspond with the Instruction TCM Region Register.

Table 3-47 Instruction TCM region register bit functions

| Bits    | Field        | Function                                                                                                                                                                                                                                                                                                     |
|---------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:12] | Base address | Base address. Defines the physical base address of the Instruction TCM. The base address must be aligned to the size of the Instruction TCM. Any bits in the range $[(\log_2(\text{RAMSize})-1):12]$ are ignored. The base address is 0 at Reset.                                                            |
| [11:7]  | -            | UNP on reads, SBZ on writes                                                                                                                                                                                                                                                                                  |
| [6:2]   | Size         | Size. Defines the size of the Instruction TCM on reads.<br>On writes this field is ignored.<br>b00000 = 0KB<br>b00011 = 4KB<br>b00100 = 8KB<br>b00101 = 16KB<br>b00110 = 32KB<br>b00111 = 64KB<br>b01000 = 128KB<br>b01001 = 256KB.<br>For more information, see <i>Tightly-coupled memory</i> on page 7-12. |
| [1]     | SBZ          | Should Be Zero                                                                                                                                                                                                                                                                                               |
| [0]     | En           | Enable. Enables or disables the Instruction TCM.<br>0 = disabled<br>1 = enabled.                                                                                                                                                                                                                             |

The value of the En bit at Reset depends on the **INITRAM** signal:

- **INITRAM** LOW sets En to 0
- **INITRAM** HIGH sets En to 1

When **INITRAM** is HIGH this enables the Instruction TCM directly from reset, with a Base address of 0x00000000. When the processor comes out of reset, it executes the instructions in the Instruction TCM instead of fetching instructions from external memory.

To use the Instruction TCM Region Register read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c9
- CRm set to c1
- Opcode\_2 set to 1.

For example:

MRC p15, 0, <Rd>, c9, c1, 1; Read Instruction TCM Region Register  
MCR p15, 0, <Rd>, c9, c1, 1; Write Instruction TCM Region Register

### 3.2.23 c13, Process ID Register

The purpose of this register is to hold a process *IDentification* (ID) value for the process running currently.

This register is used by the *Embedded Trace Macrocell* (ETM) and by the debug logic. Its value can be broadcast by the ETM to indicate the process that is running currently. You must program each process with a unique number.

Process ID value can also be used to enable process dependent breakpoints and instructions.

The Process ID Register is:

- in CP15 c13
- a 32-bit read/write register
- accessible in privileged modes only.

Figure 3-43 shows the arrangement of bits in the register.

### Figure 3-43 Format of the Process ID Register

To use the Process ID Register read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c13
- CRm set to c0
- Opcode\_2 set to 1.

For example:

```
MRC p15, 0, <Rd>, c13, c0, 1 ;Read Process ID Register
MCR p15, 0, <Rd>, c13, c0, 1 ;Write Process ID Register
```

You must:

- Ensure that software executes a Drain Write Buffer operation before changes to this register. This ensures that all accesses are related to the correct process ID.

- Execute an IMB instruction immediately after changes to the Process ID Register.
- Program each process with a unique number to ensure that ETM can correctly distinguish between processes.

### 3.2.24 c15, Data Cache Debug Register

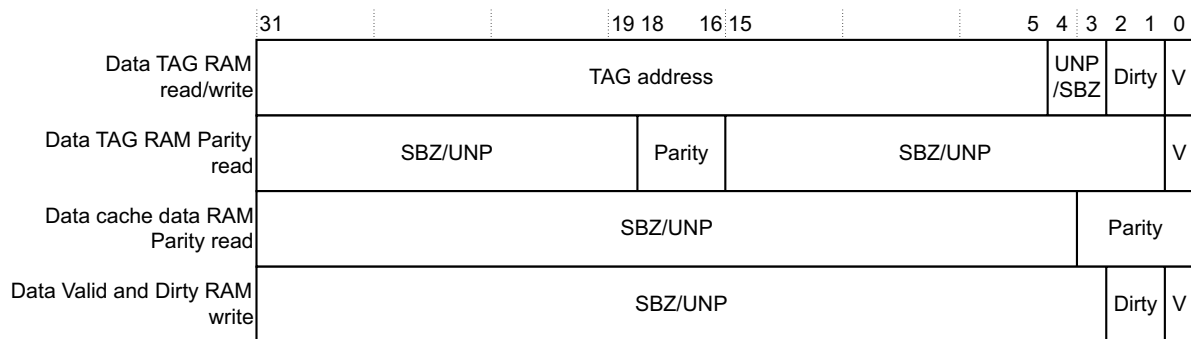

The purpose of the Data Cache Debug Register is to hold data:

- that is returned on a data Tag RAM read operation
- for a data Tag RAM write operation
- that is returned on a data cache Data RAM Parity read operation
- that is returned on a data Tag RAM Parity read operation
- for a data Valid and Dirty RAM write operation.

The Data Cache Debug Register is:

- in CP15 c15
- a 32-bit read/write register
- accessible in privileged modes only.

Figure 3-44 shows the bit arrangement of the Data Cache Debug Register when retrieving or registering data as a result of the read/write operations.

### Figure 3-44 Format s of the Data Cache Debug Register

Table 3-48 to shows how the bit values correspond with the Data Cache Debug Register functions as a result of Data Tag RAM read/write operation.

**Table 3-48 Data Cache Debug Register bit arrangement after a Data Tag RAM read/write operation**

| Bits   | Field       | Function                                                                                                                                 |
|--------|-------------|------------------------------------------------------------------------------------------------------------------------------------------|
| [31:5] | Tag address | Holds the Tag address for the cache way.                                                                                                 |
| [4:3]  | SBZ/UNP     | Should Be Zero or Unpredictable.                                                                                                         |
| [2:1]  | Dirty       | On a read holds the value of the Dirty bits from the data Tag RAM.<br>On a write holds the value of the Dirty bits for the data Tag RAM. |
| [0]    | V           | On a read holds the value of the Valid bit from the data Tag RAM.<br>On a write holds the value of the Valid bit for the data Tag RAM.   |

Table 3-49 shows how the bit values correspond with the Data Cache Debug Register functions as a result of Data Tag RAM parity read operation.

**Table 3-49 Data Cache Debug Register bit arrangement after a Data Tag RAM parity read operation**

| Bits    | Field   | Function                                           |
|---------|---------|----------------------------------------------------|
| [31:19] | SBZ/UNP | Should Be Zero or Unpredictable                    |
| [18:16] | Parity  | Holds the value of parity bits the Data Tag RAM    |
| [15:1]  | SBZ/UNP | Should Be Zero or Unpredictable                    |
| [0]     | V       | Holds the value of valid bit from the Data Tag RAM |

Table 3-50 shows how the bit values correspond with the Data Cache Debug Register functions as a result of a Data Cache Data RAM parity read operation.

**Table 3-50 Data Cache Debug Register bit arrangement after a Data Cache Data RAM parity read operation**

| Bits   | Field   | Function                                                    |
|--------|---------|-------------------------------------------------------------|
| [31:4] | SBZ/UNP | Should Be Zero or Unpredictable                             |
| [3:0]  | Parity  | Holds the value of the parity bits from Data Cache Data RAM |

Table 3-51 shows how the bit values correspond with the Data Cache Debug Register functions as a result of a Data Valid and Dirty RAM write operation.

**Table 3-51 Data Cache Debug Register bit arrangement after a Data Valid and Dirty RAM write operation**

| Bits   | Field   | Function                                                           |
|--------|---------|--------------------------------------------------------------------|
| [31:3] | SBZ/UNP | Should Be Zero or Unpredictable                                    |
| [2:1]  | Dirty   | Holds the value of the Dirty bits for the Data Valid and Dirty RAM |
| [0]    | V       | Holds the value of the Valid bit for the Data Valid and Dirty RAM  |

To use the Data Cache Debug Register read or write CP15 with:

```
MRC p15, 3, <Rd>, c15, c0, 0 ;Read Data Cache Debug Register
MCR p15, 3, <Rd>, c15, c0, 0 ;Write Data Cache Debug Register
```

For read operations, data from the cache is transferred to the Data Cache Debug Register, which is then read by the relevant instruction.

For write operations, the data to the cache is written to the Data Cache Debug Register. The write operation instruction then writes the data to the cache.

**3.2.25 c15, Instruction Cache Debug Register**

The purpose of the Instruction Cache Debug Register is to hold the data:

- that is returned on an Instruction cache Tag RAM read operation
- for an Instruction cache Tag RAM write operation
- that is returned on an Instruction cache Tag RAM Parity read operation
- that is returned on an Instruction Cache Data RAM read operation
- for an instruction write operation to the Cache Data RAM
- that is returned on an Instruction Cache Data RAM Parity read operation.

The Instruction Cache Debug Register is:

- in CP15 c15
- a 32-bit read-only register
- accessible in privileged modes only.

Figure 3-45 on page 3-89 shows the bit arrangement of the Instruction Cache Debug Register when retrieving or registering data as a result of instruction cache debug and software access read/write operations.

|  |    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Figure 3-45 Formats of the Instruction Cache Debug Register

Table 3-52 shows how the bit values correspond with the Instruction Cache Debug Register functions as a result of Instruction cache Tag RAM read/write operation.

Table 3-52 Instruction Cache Debug Register bit arrangement after an Instruction cache Tag RAM read/write operation

| Bits   | Field       | Function                                                                                                                                                      |
|--------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:5] | Tag address | Contains the address of the instruction.                                                                                                                      |
| [4:0]  | SBZ/UNP     | Should Be Zero or Unpredictable.                                                                                                                              |
| [0]    | Valid       | When reading holds the value of valid bit from the Instruction cache Tag RAM.<br>When writing holds the value of valid bit for the Instruction cache Tag RAM. |

Table 3-53 shows how the bit values correspond with the Instruction Cache Debug Register functions as a result of Instruction cache Tag RAM Parity read operation.

Table 3-53 Instruction Cache Debug Register bit arrangement after an Instruction cache Tag RAM parity read operation

| Bit     | Field   | Function                                                          |
|---------|---------|-------------------------------------------------------------------|
| [31:19] | SBZ/UNP | Should Be Zero or Unpredictable                                   |
| [18:16] | Parity  | Holds the value of Parity bits from the Instruction cache Tag RAM |
| [15:1]  | SBZ/UNP | Should Be Zero or Unpredictable                                   |
| [0]     | V       | Holds the value of valid bit from the Instruction cache Tag RAM   |

Table 3-54 shows how the bit values correspond with the Instruction Cache Debug Register functions as a result of Instruction cache Tag RAM parity read operation.

**Table 3-54 Instruction Cache Debug Register bit arrangement after an Instruction Cache Data RAM parity read operation**

| Bits   | Field   | Function                                                |
|--------|---------|---------------------------------------------------------|
| [31:4] | SBZ/UNP | Should Be Zero or Unpredictable                         |
| [3:0]  | Parity  | Holds the value of the parity bits from the parity bits |

To use the Instruction Cache Debug Register read or write CP15 with:

- Opcode\_1 set to 3
- CRn set to c15
- CRm set to c6
- Opcode\_2 set to 3.

For example:

```
MRC p15, 3, <Rd>, c15, c0, 1 ;Read Instruction Cache Debug Register
MCR p15, 3, <Rd>, c15, c0, 1 ;Write Instruction Cache Debug Register
```

For read operations, data from the cache or Instruction TCM is transferred to the Instruction Cache Debug register, which is then read by the relevant instruction.

For write operations, the data to the cache is written to the Instruction Cache Debug register, The write operation instruction then writes the data to the cache.

3.2.26 c15, Data cache Tag RAM operation

The purpose of the data cache Tag RAM operation is to:

- read the data cache Tag RAM contents and write into the Data Cache Debug Register.
- write into the Data Cache Debug Register and write into the Data Tag RAM.

The Data Tag RAM read/write operation is accessible in privileged modes only.

Figure 3-46 shows the bit arrangement for the Data Tag RAM read/write operation.

Figure 3-46 Data Tag RAM read/write operation format

Table 3-55 shows how the bit values correspond with the Data Tag RAM read/write operation.

Table 3-55 Data Tag RAM read/write operation bit functions

| Bits                                   | Field   | Function                        |
|----------------------------------------|---------|---------------------------------|
| [31-32-A <sup>a</sup> ]                | Way     | Holds the Way value             |
| [31-A <sup>a</sup> -S <sup>b</sup> +5] | SBZ/UNP | Should Be Zero or Unpredictable |
| [S <sup>b</sup> +4-5]                  | Set     | Holds the Set value             |
| [4:0]                                  | SBZ/UNP | Should Be Zero or Unpredictable |

- a. A is logarithm base 2 of the cache associativity, rounded up to an integer. The Cache Type Register holds this parameter.
- b. S is the logarithm base 2 of the number of sets in the cache. The Cache Type Register holds this parameter.

To read the Data Tag RAM:

- write CP15 with:  
MCR p15, 3, <Rd>, c15, c2, 0 ;Data Tag RAM read operation
- Transfer data to the Data Cache Debug Register to the core:  
MRC p15, 3, <Rd>, c15, c0, 0 ;Read Data Cache Debug Register

To write data to the Data Tag RAM:

- Transfer data to the Data Cache Debug Register:  
MCR p15, 3, <Rd>, c15, c0, 0 ;Write Data Cache Debug Register
- write CP15 with:  
For example:  
MCR p15, 7, <Rd>, c15, c2, 0 ;Data Tag RAM write operation

3.2.27 c15, Tag RAM parity read operation

The purpose of the Tag RAM parity read operation is to read Data or Instruction cache Tag RAM parity bits into the respective Cache Debug Register. The Data Tag RAM parity read operation is accessible in privileged modes only.

Figure 3-47 shows the bit arrangement for the Data Tag RAM parity read operation.

Figure 3-47 Tag RAM parity read operation format

Table 3-56 shows how the bit values correspond with the Tag RAM parity read operation.

Table 3-56 Data Tag RAM parity read operation bit functions

| Bits                                   | Field   | Function                        |
|----------------------------------------|---------|---------------------------------|
| [31-32-A <sup>a</sup> ]                | Way     | Holds the Way value             |
| [31-A <sup>a</sup> -S <sup>b</sup> +5] | SBZ/UNP | Should Be Zero or Unpredictable |
| [S <sup>b</sup> +4-5]                  | Set     | Holds the Set value             |
| [4:0]                                  | SBZ/UNP | Should Be Zero or Unpredictable |

a. A is logarithm base 2 of the cache associativity, rounded up to an integer. The Cache Type Register holds this parameter.  
b. S is the logarithm base 2 of the number of sets in the cache. The Cache Type Register holds this parameter.

To read the Data Tag RAM parity bits:

- write CP15 with:  
MCR p15, 3, <Rd>, c15, c2, 2 ;Data Tag RAM parity read operation

- Transfer data to the Data Cache Debug Register to the core:  
MRC p15, 3, <Rd>, c15, c0, 0 ;Read Data Cache Debug Register

To read the Instruction Tag RAM parity bits:

- write CP15 with:  
MCR p15, 7, <Rd>, c15, c2, 3 ;Instruction Tag RAM parity read operation
- Transfer data to the Data Cache Debug Register to the core:  
MCR p15, 3, <Rd>, c15, c0, 0 ;Write Data Cache Debug Register

3.2.28 c15, Instruction cache Tag RAM operation

The purpose of the Instruction cache Tag RAM read operation is to:

- read the Instruction cache Tag and Valid RAMs contents and write into the Instruction Cache Debug Register.
- write into the Data Cache Debug Register and write into the Instruction Cache Tag and Valid RAMs.
- set the appropriate Master Valid Register bit.

The Instruction cache Tag RAM read operation is accessible in privileged modes only.

Figure 3-48 shows the bit arrangement for the Instruction cache Tag RAM read/write operation.

|     |         |      |     |     |     |         |   |
|-----|---------|------|-----|-----|-----|---------|---|
| 31  | 32-A    | 31-A | S+5 | S+4 | 5   | 4       | 0 |
| Way | SBZ/UNP |      |     |     | Set | SBZ/UNP |   |

Figure 3-48 Instruction cache Tag RAM read/write operation format

Table 3-57 shows how the bit values correspond with the Instruction cache Tag RAM read/write operation.

Table 3-57 Instruction cache Tag RAM read/write operation bit functions

| Bits                                   | Field   | Function                        |
|----------------------------------------|---------|---------------------------------|
| [31-32-A <sup>a</sup> ]                | Way     | Holds the Way value             |
| [31-A <sup>a</sup> -S <sup>b</sup> +5] | SBZ/UNP | Should Be Zero or Unpredictable |
| [S <sup>b</sup> +4-5]                  | Set     | Holds the Set value             |
| [4:0]                                  | SBZ/UNP | Should Be Zero or Unpredictable |

- a. A is logarithm base 2 of the cache associativity, rounded up to an integer. The Cache Type Register holds this parameter.
- b. S is the logarithm base 2 of the number of sets in the cache. The Cache Type Register holds this parameter.

---

**Note**

---

Because this operation sets the Master Valid Register bit, you must ensure that Tag RAM writes to previously uninitialized locations are in groups of eight made up from four Ways and two Set values. The Set values must be the same, except for the least significant bit, bit 5 of the operation format.

---

To read the Instruction cache Tag RAM:

- write CP15 with:  
MCR p15, 3, <Rd>, c15, c2, 1 ;Instruction cache Tag RAM read operation
- Transfer data to the Instruction Cache Debug Register to the core:  
MRC p15, 3, <Rd>, c15, c0, 1 ;Read Instruction Cache Debug Register

To write data to the Instruction cache Tag RAM:

- Transfer data to the Instruction Cache Debug Register:  
MCR p15, 3, <Rd>, c15, c0, 1 ; Write Instruction Cache Debug Register
- write CP15 with:  
MCR p15, 7, <Rd>, c15, c2, 1 ;Instruction cache Tag RAM write operation

### 3.2.29 c15, Instruction Cache Data RAM operation

The purpose of the Cache Data RAM read operation is to read/write the Instruction Cache Data Tag RAM Register contents and read/write into the Instruction Cache Debug Register. There is no direct access from the instruction cache to the register bank. The read operation enables the contents of the instruction cache to be constructed.

For software test of the instruction cache you can set a breakpoint without invalidating cache lines.

The Instruction Cache Data RAM read/write operation is accessible in privileged modes only:

Figure 3-49 on page 3-95 shows the bit arrangement for the Instruction Cache Data RAM read/write operation.

|     |         |      |     |     |     |      |   |         |   |
|-----|---------|------|-----|-----|-----|------|---|---------|---|
| 31  | 32-A    | 31-A | S+5 | S+4 | 5   | 4    | 2 | 1       | 0 |
| Way | SBZ/UNP |      |     |     | Set | Word |   | SBZ/UNP |   |

Figure 3-49 Instruction Cache Data RAM read/write operation format

Table 3-58 shows how the bit values correspond with the Instruction Cache Data RAM read/write operation.

Table 3-58 Instruction Cache Data RAM read/write operation bit functions

| Bits                                   | Field   | Function                                    |
|----------------------------------------|---------|---------------------------------------------|
| [31-32-A <sup>a</sup> ]                | Way     | Holds the Way value                         |
| [31-A <sup>a</sup> -S <sup>b</sup> +5] | SBZ/UNP | Should Be Zero or Unpredictable             |
| [S <sup>b</sup> +4-5]                  | Set     | Holds the Set value                         |
| [4:2]                                  | Word    | Holds the Word position within a cache line |
| [1:0]                                  | SBZ/UNP | Should Be Zero or Unpredictable             |

- a. A is logarithm base 2 of the cache associativity, rounded up to an integer. The Cache Type Register holds this parameter.
- b. S is the logarithm base 2 of the number of sets in the cache. The Cache Type Register holds this parameter.

To read Instruction Cache Data RAM:

- write CP15 with:  
MCR p15, 3, <Rd>, c15, c4, 1 ;Instruction Cache Data RAM read operation
- Transfer data to the Instruction Cache Debug Register to the core:  
MRC p15, 3, <Rd>, c15, c0, 1 ;Read Instruction Cache Debug Register

To write Instruction Cache Data RAM:

- Transfer data to the Instruction Cache Debug Register from the core:  
MCR p15, 3, <Rd>, c15, c0, 1 ;Write Instruction Cache Debug Register
- write CP15 with:  
For example:  
MCR p15, 7, <Rd>, c15, c4, 1 ;Instruction Cache Data RAM write operation

3.2.30 c15, Cache Data RAM parity read operations

The purpose of the cache data RAM parity read operations is to read data or instruction cache data RAM parity bits into the respective Cache Debug Register.

The Data Tag RAM parity read operation is accessible in privileged modes only.

Figure 3-50 shows the bit arrangement for the Cache Data RAM parity read operation.

Figure 3-50 Cache Data RAM parity read operation format

Table 3-59 shows how the bit values correspond with the Cache Data RAM parity read operations.

Table 3-59 Cache Data RAM parity read operation bit functions

| Bits                                   | Field   | Function                        |
|----------------------------------------|---------|---------------------------------|
| [31-32-A <sup>a</sup> ]                | Way     | Holds the Way value             |
| [31-A <sup>a</sup> -S <sup>b</sup> +5] | SBZ/UNP | Should Be Zero or Unpredictable |
| [S <sup>b</sup> +4-5]                  | Set     | Holds the Set value             |
| [4:0]                                  | SBZ/UNP | Should Be Zero or Unpredictable |

- a. A is logarithm base 2 of the cache associativity, rounded up to an integer. The Cache Type Register holds this parameter.
- b. S is the logarithm base 2 of the number of sets in the cache. The Cache Type Register holds this parameter.

To read the Data Cache Data RAM parity bits:

- write CP15 with:  
MCR p15, 3, <Rd>, c15, c2, 2 ; Data Cache Data RAM parity read operation
- Transfer data to the Data Cache Debug Register to the core:  
MRC p15, 3, <Rd>, c15, c0, 0 ; Read Data Cache Debug Register

To read the Instruction Cache Data RAM parity:

- write CP15 with:  
MCR p15, 7, <Rd>, c15, c2, 1 ; I-Cache Data RAM parity read operation
- Transfer data to the Data Cache Debug Register:  
MCR p15, 3, <Rd>, c15, c0, 0 ; Write Data Cache Debug Register

### 3.2.31 c15, Instruction Cache Master Valid Register

The purpose of this register is to mask the Valid bits held in the Instruction Valid RAM for the instruction cache. This enables the processor to perform a single cycle invalidation of the cache without the use of special resettable RAM cells.

The Instruction Cache Master Valid Register is:

- in CP15 c15
- a 32-bit read/write register
- accessible in privileged modes only.

The number of Master Valid bits is a function of the cache size. There is one Master Valid bit for each 8 cache lines:

$$\text{MasterValid bits} = \frac{\text{Cache size}}{\text{line length in bytes} \times 8}$$

For instance, there are 64 Master Valid bits for a 16KB cache. You can access Master Valid bits through 32-bit registers indexed using Opcode\_2. The maximum number of 32-bit registers required for the largest cache size, 64K, is 8. Master Valid bits fill the registers from the LSB of the lowest numbered register upwards.

Unimplemented Valid bits are Unpredictable for reads and *Should Be Zero or Preserved* (SBZP) for writes.

To use the Instruction Cache Master Valid Register write CP15 with:

```
MRC p15, 3, <Rd>, c15, c8, {7-0} ;Read Instruction Cache Master Valid
MCR p15, 3, <Rd>, c15, c8, {7-0} ;Write Instruction Cache Master Valid
```

The Opcode\_2 field is the bank number in the range 7-0. The bank number that you use for capturing cache Master Valid bits is one less than the number of times 8KB divides into the cache size, or 0 if the cache size is less than 8KB.

### 3.2.32 c15, Data Cache Master Valid Register

The purpose of this register is to mask the Valid bits held in the Data Valid RAM for the data cache. This enables the processor to perform a single cycle invalidation of the cache without the use of special resettable RAM cells.

The Data Cache Master Valid Register is:

- in CP15 c15
- a 32-bit read/write register
- accessible in privileged modes only.

The number of Master Valid bits is a function of the cache size. There is one Master Valid bit for each 8 cache lines:

$$\text{MasterValid bits} = \frac{\text{Cache size}}{\text{line length in bytes} \times 8}$$

For instance, there are 64 Master Valid bits for a 16KB cache. You can access Master Valid bits through 32-bit registers indexed using Opcode\_2. The maximum number of 32-bit registers required for the largest cache size, 64K, is 8. Master Valid bits fill the registers from the LSB of the lowest numbered register upwards.

Unimplemented Valid bits are Unpredictable for reads and *Should Be Zero or Preserved* (SBZP) for writes.

To use the Data Cache Master Valid Register write CP15 with:

```
MRC p15, 3, <Rd>, c15, c12, {7-0} ;Read Data Cache Master Valid Register
MCR p15, 3, <Rd>, c15, c12, {7-0} ;Write Data Cache Master Valid Register
```

The Opcode\_2 field is the bank number in the range 7-0. The bank number that you use for capturing cache Master Valid bits is one less than the number of times 8KB divides into the cache size, or 0 if the cache size is less than 8KB.

3.2.33 c15, Cache Debug Control Register

The purpose of the Cache Debug Control Register is for a debugger to control access to the cache.

The Cache Debug Control Register is:

- in CP15 c15
- a 32-bit read/write register
- accessible in privileged modes only.

Figure 3-51 shows the bit arrangement for the Cache Debug Control Register.

Figure 3-51 Cache Debug Control Register format

Table 3-60 shows how the bit values correspond to the Cache Debug Control Register.

Table 3-60 Cache Debug Control Register bit functions

| Bits   | Field      | Function                                                                                                                                               |
|--------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31:3] | UNP or SBZ | Reserved                                                                                                                                               |
| [2]    | WT         | Defines write-through behavior for regions marked as write-back:<br>1 = Force write-through<br>0 = Do not force write-through, normal operation        |
| [1]    | IL         | Enables or disables Instruction cache linefill:<br>1 = Instruction cache linefill disabled<br>0 = Instruction cache linefill enabled, normal operation |
| [0]    | DL         | Enables or disables data cache linefill:<br>1 = Data cache linefill disabled<br>0 = Data cache linefill enabled, normal operation                      |

To use the Cache Debug Control Register read or write CP15 with:

```
MRC p15, 7, <Rd>, c15, c0, 0;Read cache debug control register
MCR p15, 7, <Rd>, c15, c0, 0;Write cache debug control register
```

3.2.34 c15, Data Cache Valid RAM and Dirty RAM bit write operation

The purpose of the Data Cache Valid RAM and Dirty RAM bit write operation is to write from the Data Cache Debug Register into the Data Cache Valid RAM and Dirty RAM.

The Data Cache Valid RAM and Dirty RAM bit write operation is accessible in privileged modes only

Figure 3-52 shows the bit arrangement for the Data Cache Valid RAM and Dirty RAM bit write operation.

Figure 3-52 Data Cache Valid RAM and Dirty RAM bit write operation format

Table 3-61 shows how the bit values correspond with the Data Cache Valid RAM and Dirty RAM bit write operation.

**Table 3-61 Data Cache Valid RAM and Dirty RAM bit write operation bit functions**

| Bits                                   | Field   | Function                        |
|----------------------------------------|---------|---------------------------------|
| [31-32-A <sup>a</sup> ]                | Way     | Holds the Way value             |
| [31-A <sup>a</sup> -S <sup>b</sup> +5] | SBZ/UNP | Should Be Zero or Unpredictable |
| [S <sup>b</sup> +4-5]                  | Set     | Holds the Set value             |
| [4:0]                                  | SBZ/UNP | Should Be Zero or Unpredictable |

- a. A is logarithm base 2 of the cache Associativity, rounded up to an integer. The Cache Type Register holds this parameter.
- b. S is the logarithm base 2 of the number of sets in the cache. The Cache Type Register holds this parameter.

To write data to the Data Cache Valid RAM and Dirty RAM bit write operation:

- Transfer data to the Data Cache Debug Register:  
MCR p15, 3, <Rd>, c15, c0, 0 Write Data Cache Debug Register
- write CP15 with:

MCR p15, 7, <Rd>, c15, c2, 2; Data Cache Valid RAM and Dirty RAM bit write operation

**3.2.35 c15, Performance Monitor Control Register**

The purpose of the Performance Monitor Control Register is to control the operation of:

- the Cycle Counter Register
- the Count Register 0
- the Count Register 1.

The Performance Monitor Control Register is:

- in CP15 c15
- a 32-bit read/write register
- accessible in privileged modes only.

Figure 3-53 on page 3-101 shows the bit arrangement for the Performance Monitor Control Register.

Figure 3-53 Performance Monitor Control Register format

Table 3-62 shows how the bit values correspond with the Performance Monitor Control Register.

Table 3-62 Performance Monitor Control Register bit functions

| Bits    | Field     | Function                                                                                                                                                                                                                      |
|---------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31]    | SBZ/UNP   | SBZ on writes, UNP on reads,                                                                                                                                                                                                  |
| [30]    | FCC       | Enable and disable clock counter FIQ interrupt reporting:<br>0 = disable interrupt<br>1 = Enable interrupt.                                                                                                                   |
| [29]    | FC1       | Enable and disable performance counter 1 FIQ interrupt reporting:<br>0 = disable interrupt<br>1 = Enable interrupt.                                                                                                           |
| [28]    | FC0       | Enable and disable performance counter 0 FIQ interrupt reporting:<br>0 = disable interrupt<br>1 = Enable interrupt.                                                                                                           |
| [27:20] | EvtCount0 | Identifies the source of events for Count Registers. Table 3-63 on page 3-103 shows the values, functions and EVNTBUS bit position for the event Count Register 0                                                             |
| [19:12] | EvtCount1 | Identifies the source of events for Count Registers. Table 3-63 on page 3-103 shows the values and the bit functions for the event Count Register 1                                                                           |
| [11]    | X         | Enable Export of the events to the event bus to an external monitoring block, such as the ETM to trace events:<br>0 = Export disabled, <b>EVNTBUS</b> held at 0x0<br>1 = Export enabled, <b>EVNTBUS</b> driven by the events. |

**Table 3-62 Performance Monitor Control Register bit functions (continued)**

| <b>Bits</b> | <b>Field</b> | <b>Function</b>                                                                                                                                                           |
|-------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [10]        | OCC          | Cycle Counter Register overflow flag:<br>For reads:<br>0 = no overflow (reset value)<br>1 = overflow has occurred.<br>For writes:<br>0 = no effect<br>1 = clear this bit. |

| [8]         | OC0          | Count Register 0 overflow flag:<br>For reads:<br>0 = no overflow (reset)<br>1 = overflow has occurred.<br>For writes:<br>0 = no effect<br>1 = clear this bit.             |
| [7]         | SBZ/UNP      | SBZ on write, UNP on reads                                                                                                                                                |
| [6]         | ICC          | Used to enable and disable Cycle Counter interrupt reporting:<br>0 = disable interrupt<br>1 = Enable interrupt.                                                           |
| [5]         | IC1          | Enable and disable Cycle Counter 1 interrupt reporting:<br>0 = disable interrupt<br>1 = Enable interrupt.                                                                 |
| [4]         | IC0          | Enable and disable Count Register 0 interrupt reporting:<br>0 = disable interrupt<br>1 = Enable interrupt.                                                                |

**Table 3-62 Performance Monitor Control Register bit functions (continued)**

| Bits | Field | Function                                                                                                                                       |
|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------|
| [3]  | D     | Cycle count divider:<br>1 = Counts every 64th processor clock cycle<br>0 = Counts every processor clock cycle.                                 |
| [2]  | C     | Cycle Counter Register Reset:<br>1 = Reset the Cycle Counter Register to 0x0<br>0 = No action Reset on write, Unpredictable on read            |
| [1]  | P     | Count Register 1 and Count Register 0 Reset:<br>1 = Reset both Count Registers to 0x0.<br>0 = No action Reset on write, Unpredictable on read. |
| [0]  | E     | Enable all counters:<br>1 = All counters enabled.<br>0 = All counters disabled.                                                                |

The Performance Monitor Control Register:

- controls which events Count Register 0 and Count Register 1 count
- indicates which counter overflowed
- enables and disables the report of interrupts
- extends Cycle Count Register counting by six more bits, cycles between counter rollover =  $2^{38}$
- resets all counters to zero
- enables the entire performance monitoring mechanism.

Table 3-63 shows the events that can be monitored using the Performance Monitor Control Register.

**Table 3-63 Performance monitoring events**

| EVNTBUS<br>bit position | Event<br>number | Event definition                                                                                                                                                                                |
|-------------------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [0]                     | 0x0             | Instruction cache miss to a cacheable location requires fetch from external memory.                                                                                                             |
| [1]                     | 0x1             | Stall because instruction buffer cannot deliver an instruction. This can indicate an instruction cache miss or an Memory miss. This event occurs every cycle in which the condition is present. |
| [2]                     | 0x2             | Stall because of a data dependency. This event occurs every cycle in which the condition is present.                                                                                            |

Table 3-63 Performance monitoring events (continued)

| EVNTBUS<br>bit position | Event<br>number | Event definition                                                                                                                                                                                                                                                                              |
|-------------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [3]                     | -               | Reserved.                                                                                                                                                                                                                                                                                     |
| [4]                     | -               | Reserved.                                                                                                                                                                                                                                                                                     |
| [5]                     | 0x5             | Branch instruction executed, branch might or might not have changed program flow.                                                                                                                                                                                                             |
| [6]                     | -               | Reserved.                                                                                                                                                                                                                                                                                     |
| [7]                     | 0x6             | Branch mispredicted.                                                                                                                                                                                                                                                                          |
| [9:8]                   | 0x7             | Instruction executed.                                                                                                                                                                                                                                                                         |
| [10]                    | 0x9             | Data cache access. Does not include Cache Operations. This event occurs for each nonsequential access to a cache line, for cacheable locations.                                                                                                                                               |
| [11]                    | 0xA             | Data cache access. Does not include Cache Operations. This event occurs for each nonsequential access to a cache line, regardless of whether or not the location is cacheable.                                                                                                                |
| [12]                    | 0xB             | Data cache miss. Does not include Cache Operations.                                                                                                                                                                                                                                           |
| [13]                    | 0xC             | Data cache write-back. This event occurs once for each half line of four words that are written back from the cache.                                                                                                                                                                          |
| [15:14]                 | 0xD             | Software changed the PC. This event occurs any time the PC is changed by software and there is not a mode change. For example, a MOV instruction with PC as the destination triggers this event. Executing a SVC from User mode does not trigger this event, because it incurs a mode change. |
| [16]                    | -               | Reserved.                                                                                                                                                                                                                                                                                     |
| [17]                    | 0x10            | Explicit external data or peripheral access. This includes cache refill, Noncachable and write-through accesses. It does not include write-backs.                                                                                                                                             |
| [18]                    | 0x11            | Stall because of a full Load Store Unit request queue. This event takes place each clock cycle in which the condition is met. A high incidence of this event indicates the BCU is often waiting for transactions to complete on the external bus.                                             |
| [19]                    | 0x12            | The number of times the Write Buffer was drained because of a Drain Write Buffer command or a Strongly Ordered operation to data or peripheral interface.                                                                                                                                     |
| -                       | 0x13            | The number of cycles FIQ interrupts are disabled.                                                                                                                                                                                                                                             |
| -                       | 0x14            | The number of cycles IRQ interrupts are disabled.                                                                                                                                                                                                                                             |
| -                       | 0x20            | ETM external event to be monitor is enabled.                                                                                                                                                                                                                                                  |
| -                       | 0x21            | ETM external event to be monitor is enabled.                                                                                                                                                                                                                                                  |

Table 3-63 Performance monitoring events (continued)

| EVNTBUS<br>bit position | Event<br>number     | Event definition                                                                                                                                                              |
|-------------------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -                       | 0x22                | If both <b>ETMEXTOUT[0]</b> and <b>ETMEXTOUT[1]</b> signals are asserted then the count is incremented by two. If either signal is asserted then the count increments by one. |
| -                       | 0x30                | Instruction cache Tag or Valid RAM parity error.                                                                                                                              |
| -                       | 0x31                | Instruction cache RAM parity error.                                                                                                                                           |
| -                       | 0x32                | Data cache Tag or Valid RAM parity error.                                                                                                                                     |
| -                       | 0x33                | Data cache RAM parity error.                                                                                                                                                  |
| -                       | 0x34                | ITCM error.                                                                                                                                                                   |
| -                       | 0x35                | DTCM Error.                                                                                                                                                                   |
| -                       | 0x36                | Procedure return address popped off the return stack.                                                                                                                         |
| -                       | 0x37                | Procedure return address popped off the return stack has been incorrectly predicted by the PFU.                                                                               |
| -                       | 0x38                | Data cache Dirty RAM parity error                                                                                                                                             |
| -                       | 0xFF                | An increment each cycle.                                                                                                                                                      |
| -                       | All other<br>values | Reserved. Unpredictable behavior.                                                                                                                                             |

To access the Performance Monitor Control Register read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c15
- CRm set to c12
- Opcode\_2 set to 0.

For example:

MRC p15, 0, <Rd>, c15, c12, 0; Read Performance Monitor Control Register  
MCR p15, 0, <Rd>, c15, c12, 0; Write Performance Monitor Control Register

If this unit generates an interrupt, the ARM1156T2F-S processor asserts the pin **nPMUIRQ** and **nPMUFIQ** as appropriate. You can route these pins to an external interrupt controller for prioritization and masking. This is the only mechanism by which the interrupt is signalled to the core.

You can only enable or disable the performance metrics interrupts **nPMUIRQ** and **nPMUFIQ** if the metrics counters are enabled, that is Performance Monitor Control Register bit [0] is set to 1.

Follow steps 1. and 2. to de-assert **nPMUIRQ** and **nPMUFIQ**:

1. Write to the Performance Monitor Control Register to clear the interrupt enable bit.
2. Write to the Performance Monitor Control Register to disable the counter.

There is a delay of three cycles between an enable of the counter and the start of the event counter. The information used to count events is taken from various pipeline stages. This means that the absolute counts recorded might vary because of pipeline effects. This has negligible effect except in cases where the counters are enabled for a very short time.

In addition to the two counters within the ARM1156T2F-S processor, each of the events that Table 3-63 on page 3-103 shows is available on an external bus, **EVENTBUS[19:0]**. You can connect this bus to the ETM unit or other external trace hardware to enable the events to be monitored. If you do not want this functionality, set the X bit in the Performance Monitor Control Register to 0.

### 3.2.36 c15, Cycle Counter Register

The purpose of the Cycle Counter Register is to count the core clock cycles.

The Cycle Counter Register:

- is in CP15 c15
- is a 32-bit counter
- can trigger an interrupt on overflow.

The Cycle Counter Register bits [31:0] contain the count value.

You can use it in conjunction with the Performance Monitor Control Register and the two Counter Registers to provide a variety of useful metrics that enable you to optimize system performance.

To access Cycle Counter Register read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c15
- CRm set to c12
- Opcode\_2 set to 1.

For example:

```
MRC p15, 0, <Rd>, c15, c12, 1 ;Read Cycle Counter Register
MCR p15, 0, <Rd>, c15, c12, 1 ;Write Cycle Counter Register
```

The value in the Cycle Counter Register is Unpredictable at Reset.

You can use the Performance Monitor Control Register to set the Cycle Counter Register to zero.

You can use the Performance Monitor Control Register to configure the Cycle Counter Register to count every 64th clock cycle.

### 3.2.37 c15, Count Register 0

The purpose of the Count Register 0 is to count instances of an event that the Performance Monitor Control Register selects:

The Count Register 0:

- is in CP15 c15
- a 32-bit counter
- counts up and can trigger an interrupt on overflow.

Count Register 0 bits [31:0] contain the count value.

You can use this register in conjunction with the Performance Monitor Control Register, the Cycle Count Register, and Count Register 0 to provide a variety of useful metrics that enable you to optimize system performance.

To access Count Register 1 read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c15
- CRm set to c12
- Opcode\_2 set to 2.

For Example:

```
MRC p15, 0, <Rd>, c15, c12, 2 ;Read Count Register 0
MCR p15, 0, <Rd>, c15, c12, 2 ;Write Count Register 0
```

The value in Count Register 0 is 0 at Reset.

You can use the Performance Monitor Control Register to set Count Register 0 to zero.

### 3.2.38 c15, Count Register 1

The purpose of the Count Register 1 is to count instances of an event that the Performance Monitor Control Register selects.

The Count Register 1:

- is in CP15 c15
- a 32-bit counter
- counts up and can trigger an interrupt on overflow.

Count Register 1 bits [31:0] contain the count value.

You can use this register in conjunction with the Performance Monitor Control Register, the Cycle Count Register, and Count Register 0 to provide a variety of useful metrics that enable you to optimize system performance.

To access Count Register 1 read or write CP15 with:

- Opcode\_1 set to 0
- CRn set to c15
- CRm set to c12
- Opcode\_2 set to 3.

For Example:

```
MRC p15, 0, <Rd>, c15, c12, 3; Read Count Register 1
MCR p15, 0, <Rd>, c15, c12, 3; Write Count Register 1
```

The value in Count Register 1 is 0 at Reset.

You can use the Performance Monitor Control Register to set Count Register 0 to zero.

### 3.3 System control coprocessor reference data

This sections lists reference data for:

- *Instruction summary.*

#### 3.3.1 Instruction summary

Table 3-64 Shows a summary of CP instructions that the processor can use.

**Table 3-64 Summary of CP15 instructions**

| Instruction                        | Operation                                                    | Reference |
|------------------------------------|--------------------------------------------------------------|-----------|
| MRC p15, 0, <Rd>, c0, c0, 0        | Read ID Code                                                 | page 3-18 |
| MRC p15, 0, <Rd>, c0, c0, 1        | Read Cache Type                                              | page 3-20 |
| MRC p15, 0, <Rd>, c0, c0, 2        | Read TCM status                                              | page 3-24 |
| MRC p15, 0, <Rd>, c0, c0, 4        | Read MPU                                                     | page 3-25 |
| MRC p15, 0, <Rd>, c0, c1-c2, {0-7} | Read Feature Id Registers                                    | page 3-26 |
| MRC p15, 0, <Rd>, c1, c0, 0        | Read Control Register configuration data                     | page 3-46 |
| MCR p15, 0, <Rd>, c1, c0, 0        | Write Control Register configuration data                    |           |
| MRC p15, 0, <Rd>, c1, c0, 1        | Read Auxiliary Control Register configuration data           | page 3-50 |
| MCR p15, 0, <Rd>, c1, c0, 1        | Write Auxiliary Control Register configuration data          |           |
| MRC p15, 0, <Rd>, c1, c0, 2        | Read Coprocessor Access Control Register configuration data  | page 3-53 |
| MCR p15, 0, <Rd>, c1, c0, 2        | Write Coprocessor Access Control Register configuration data |           |
| MRC p15, 0, <Rd>, c5, c0, 0        | Read Data Fault Status Register                              | page 3-54 |
| MCR p15, 0, <Rd>, c5, c0, 0        | Write Data Fault Status Register                             |           |
| MRC p15, 0, <Rd>, c5, c0, 1        | Read Instruction Fault Status Register                       | page 3-56 |
| MCR p15, 0, <Rd>, c5, c0, 1        | Write Instruction Fault Status Register                      |           |
| MRC p15, 0, <Rd>, c6, c0, 0        | Read Fault Address Register                                  | page 3-57 |
| MCR p15, 0, <Rd>, c6, c0, 0        | Write Fault Address Register                                 |           |
| MRC p15, 0, <Rd>, c6, c0, 1        | Read Watchpoint Fault Address Register                       | page 3-57 |
| MCR p15, 0, <Rd>, c6, c0, 1        | Write Watchpoint Fault Address Register                      |           |
| MRC p15, 0, <Rd>, c6, c0, 2        | Read Instruction Fault Address Register                      | page 3-58 |
| MCR p15, 0, <Rd>, c6, c0, 2        | Write Instruction Fault Address Register                     |           |

**Table 3-64 Summary of CP15 instructions (continued)**

| <b>Instruction</b>           | <b>Operation</b>                                         | <b>Reference</b> |
|------------------------------|----------------------------------------------------------|------------------|
| MRC p15, 0, <Rd>, c6, c1, 0  | Read Data Region Base Address Register                   | page 3-60        |
| MCR p15, 0, <Rd>, c6, c1, 0  | Write Data Region Base Address Register                  |                  |

# Chapter 4

## Prefetch Unit

This chapter describes how the *PreFetch Unit* (PFU), in conjunction with the core, uses program flow prediction to locate branches in the instruction stream and the strategies used to determine if a branch is likely to be taken or not. It also describes the two architecturally-defined SVC functions the processor requires for backwards-compatibility with earlier architectures to flush the *Prefetch Unit* (PFU) buffers. It contains the following sections:

- *About the prefetch unit* on page 4-2
- *Branch prediction* on page 4-3
- *Return stack* on page 4-6
- *Instruction Memory Barrier (IMB) instruction* on page 4-7.

## 4.1 About the prefetch unit

The purpose of the PFU is to:

- Perform speculative fetch instructions ahead of the core by predicting the outcome of branch instructions.
- Detect Thumb-2 instructions and present these to the core as a single instruction. The Thumb-2 IT instruction is pre-processed by the PFU to aid the core in efficient implementation.
- Manage CP15 operations that involve the instruction cache, linefill operations, and LSU accesses into the *Instruction TCM* (ITCM). This is because the PFU drives the instruction cache and ITCM address buses. For details of CP15 instructions see Chapter 3 *System Control Coprocessor*.

The PFU fetches instructions from the memory system under the control of the core, and coprocessors. In ARM state the memory system can supply up to two instructions each cycle. In Thumb state the memory system can supply up to four instructions each cycle.

The PFU buffers up to five instructions in its FIFO. This reduces or eliminates stall cycles after a branch instruction, which increases the performance of the processor.

The PFU contains branch folding logic to reduce the average cycle time of a branch.

Program flow prediction occurs in the Prefetch Unit by:

- predicting the outcome of conditional branches using the Branch Predictor and, if they are predicted taken, calculating their destination address.
- predicting the destination of procedure returns using the Return Stack.

The core resolves the program flow predictions that the Prefetch Unit makes.

The PFU also handles the cache access multiplexing for:

- CP15 instruction handling
- data accesses to the Instruction TCM.

The PFU fetches the instruction stream as dictated by:

- the Program Counter
- the Branch Predictor
- procedure returns signaled by the Return Stack
- exceptions, instruction aborts, and interrupts signaled by the core.

## 4.2 Branch prediction

The processor uses branch prediction to reduce the core CPI loss that arises from the longer pipeline. To improve the branch prediction accuracy, the PFU uses dynamic techniques.

In ARM processors that have no PFU, the target of a branch is not known until the end of the Execute stage. At the Execute stage it is known whether or not the branch is taken. In ARM processors without a PFU, the best performance is obtained by predicting all branches as not taken and filling the pipeline with the instructions that follow the branch in the current sequential path. In this case an untaken branch requires one cycle and a taken branch requires three or more cycles.

Branch prediction enables the detection of branch instructions before they enter the core. This permits the use of a branch prediction scheme that closely models actual conditional branch core behavior.

The increased pipeline length of the ARM1156T2F-S processor makes the performance penalty of any changes in program flow, such as branches or other updates to the PC, more significant than was the case on the ARM9E core. Therefore, a significant amount of hardware is dedicated to prediction of these changes. Two major classes of program flow are addressed in the ARM1156T2F-S prediction scheme:

1. Branches, including BL, and BLX immediate, where the target address is a fixed offset from the program counter. The prediction amounts to an examination of the probability that a branch passes its condition codes.
2. Loads and Moves, writing to the PC, which can be identified as being likely to be a return from a procedure call. Two identifiable cases are:
  - Loads to the PC from an address derived from r13, the stack pointer
  - Moves to the PC derived from r14, the Link Register.

In these cases, if the calling operation can also be identified, the likely return address can be stored in a hardware implemented stack, termed a *Return Stack* (RS). Typical calling operations are BL and BLX instructions.

### 4.2.1 Enabling/disabling program flow prediction

To enable or disable program flow prediction you use the Z bit, bit 11, of CP15 Register c1. The Z bit is set to 0 on Reset. For more information see *c1, Control Register* on page 3-46. You can also control the return stack, the branch predictor, and branch folding using the Auxiliary Control Register. For more information see *c1, Auxiliary Control Register* on page 3-50.

### 4.2.2 Branch predictor

Branch prediction in the ARM1156T2F-S processor is dynamic and is based around a Global History prediction scheme. In addition, there is extra logic to handle predictions that thrash and to predict the end of long loops.

The Global History scheme is an adaptive predictor that learns the behavior of branches during execution. In the case of the ARM1156T2F-S processor it comprises multiple history tables and branch history registers that index into the tables. The history tables hold 1-bit hint values. The 1-bit hint indicates if a branch should be predicted taken or predicted not-taken based on the behavior of previous branches. In ARM state the history tables are configured as two global history tables, each of which have 256 entries. In Thumb state the history tables are configured as four global tables, each of which have 128 entries. The multiple history tables enable accurate prediction of the multiple instructions that can be supplied to the PFU from the memory system in each cycle.

For loops above a certain number of iterations the branch history is not large enough to learn the final pass through the loop in which the loop branch is not taken. The ARM1156T2F-S processor uses extra logic to learn these special not-taken predictions by storing a small number of predictions against an extended branch history.

If multiple branch histories index into the same hint value this can cause thrashing in the history table and reduce accuracy of the branch predictor. Extra logic is used to detect these cases and provide some hysteresis for the hint value. This provides most of the advantages of having a 2-bit hint value in the history table at reduced cost.

Not all branches are detected by the branch predictor. This is because not all branch destinations can be statically calculated. For dynamic branches, the hint value predicts if the branch is taken or not.

The target address is calculated statically.

The core updates the history for each occurrence of a dynamic branch. The core schedules the update when the core resolves the branch.

#### Enabling the branch predictor

To enable the branch predictor the Z bit of the CP15 Control Register and the DB of the Auxiliary Control Register bits must be set to 1. When the branch predictor is disabled, conditional branches are predicted not taken. Unconditional branches are taken by the PFU, as normal.

## Configuring the branch predictor

You can configure the branch predictor as follows:

- Prediction using the pattern history tables is always enabled when the Z and DB bits are set.
- You can enable or disable prediction using the dynamic branch predictor loop cache by setting or clearing the BL bit in the Auxiliary Control Register. If it is to be enabled the Z and DB bits must also be set.
- You can enable or disable prediction using the dynamic branch predictor pattern cache by setting or clearing the BC bit in the Auxiliary Control Register. If it is to be enabled the Z and DB bits must also be set.

### 4.2.3 Branch folding

Branch folding is a technique where, on the prediction of most branches, the branch instruction is completely removed from the instruction stream presented to the execution pipeline. Branch folding can significantly improve the performance of branches, taking the CPI for branches below 1.

The PFU performs branch folding for all predicted branches. The PFU does not perform branch folding for:

- BL and BLX instructions (to avoid losing the link)
- predicted branches onto predicted branches
- branches that are breakpointed
- branches that generate an abort when fetched.

### 4.2.4 Incorrect predictions and correction

The core resolves branches that the PFU makes at or before the Ex3 stage of the core pipeline. A misprediction causes the PFU to flush the pipeline, and fetch the correct instruction stream. If a branch is folded and mispredicted by the PFU, the instruction that follows the folded branch fails. To recover from an error whenever a potentially incorrect prediction is made, the PFU stores:

- a fall-through address in the case of a predicted taken branch instruction
- the branch target address in the case of a predicted not taken branch instruction.

The PFU passes the conditional part of any folded branch into the core. This enables the core to compare these bits with the processor flags and determine if the prediction was correct or not. If the prediction was incorrect, the core flushes the PFU and requests that prefetching begins from the stored recovery address.

For details on worst-case mispredict time see *Branches* on page 17-18.

## 4.3 Return stack

The purpose of the return stack is to predict procedural returns that are program flow changes such as loads, moves, and ALU operations. Only unconditional procedure returns are predicted.

The return stack consists of a three-entry circular buffer.

When the PFU predicts a procedure call instruction as taken the PFU pushes the return address onto the return stack. The instructions that the PFU recognizes as procedure calls are:

- for ARM instructions:
  - BL immediate conditional
  - BLX immediate unconditional
- for Thumb instructions:
  - unconditional BL immediate and BLX immediate.

When the return stack detects an unconditional return instruction, the PFU issues an instruction fetch from the location at the top of the return stack, and pops the return stack. The instructions that the PFU recognizes as procedure returns are:

- for ARM and Thumb instructions:
  - MOV pc, r14
- for ARM and Thumb 2 instructions:
  - LDR pc
  - LDM r13, {..pc..}
  - BX r14
- for Thumb instructions:
  - POP.

For conditional return instruction the PFU assumes that the condition code fails and the return instruction is not executed. The Return Stack is not popped. Return stack mispredictions can exist when:

- a conditional return instruction might pass its conditional code
- the return address might not be correct.

In addition, an empty return stack gives no prediction.

## 4.4 Instruction Memory Barrier (IMB) instruction

In some circumstances it is likely that the prefetch unit pipeline and the core pipeline contain out-of-date instructions. In these circumstances the core requires two *Instruction Memory Barrier* (IMB) instructions to flush the prefetch buffer. This maintains backwards compatibility with the ARM1020T.

To implement the two IMB instructions, you must include processor-specific code in the SVC handler:

|          |                                                                                                                                                                                                                                                                                                                                                    |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IMB      | The IMB instruction flushes all information about all instructions.                                                                                                                                                                                                                                                                                |
| IMBRange | When only a small area of code is altered before being executed the IMBRange instruction can be used to efficiently and quickly flush any stored instruction information from addresses within a small range. By flushing only the required address range information, the rest of the information remains to provide improved system performance. |

These instructions are implemented as calls to specific SVC numbers:

|          |               |
|----------|---------------|
| IMB      | SVC 0xF00000  |
| IMBRange | SVC 0xF00001. |

### 4.4.1 Generic IMB use

Use SVC functions to provide a well-defined interface between code that is independent of the ARM processor implementation it is running on and code that is specific to the ARM processor implementation it is running on.

The implementation-independent code is provided with a function that is available on all processor implementations using the SVC interface, and that can be accessed by privileged and, where appropriate, non-privileged (User mode) code.

Using SVCs to implement the IMB instructions means that any code that is written now is compatible with any future processors, even if those processors implement IMB in different ways. This is achieved by changing the operating system SVC service routines for each of the IMB SVC numbers that differ from processor to processor.

### 4.4.2 ARM1020T or later IMB implementation

For ARM1020T or later processors, executing the SVC instruction is sufficient in itself to cause IMB operation. Also, for ARM1020T or later, both the IMB and the IMBRange instructions flush all stored information about the instruction stream.

This means that all IMB instructions can be implemented in the operating system by returning from the IMB or IMBRange service routine and that the service routines can be exactly the same. The following service routine code can be used:

```
IMB_SVC_handler
IMBRange_SVC_handler
```

```
MOVS PC, R14_svc ; Return to the code after the SVC call
```

---

**Note**

In new code, you are strongly encouraged to use the IMBRange instruction whenever the changed area of code is small, even if there is no distinction between it and the IMB instruction on ARM1156T2F-S processors. Future processors might implement the IMBRange instruction in a much more efficient and faster manner, and code migrated from the ARM920T core is likely to benefit when executed on these processors.

---

### 4.4.3 Execution of IMB instructions

This section comprises three examples that show what can happen during the execution of IMB instructions. The pseudo code in the square brackets shows what happens to execute the IMB instruction (or IMBRange) in the SVC handler.

Example 4-1 shows how code that loads a program from a disk, and then branches to the entry point of that program, must execute an IMB instruction between loading the program and trying to execute it.

#### Example 4-1 Loading code from disk

---

```
IMB EQU 0xF00000
.
.
; code that loads program from disk
.
.
SVC IMB
 [branch to IMB service routine]
 [perform processor-specific operations to execute IMB]
 [return to code]
.
MOV PC, entry_point_of_loaded_program
.
.
```

---

Compiled BitBlt routines optimize large copy operations by constructing and executing a copying loop that has been optimized for the exact operation wanted. When writing such a routine an IMB is required between the code that constructs the loop and the actual execution of the constructed loop. This is shown in Example 4-2.

#### Example 4-2 Running BitBlt code

---

```
IMBRange EQU 0xF00001.
.
; code that constructs loop code
; load R0 with the start address of the constructed loop
; load R1 with the end address of the constructed loop
SVC IMBRange
 [branch to IMBRange service routine]
 [read registers R0 and R1 to set up address range parameters]
 [perform processor-specific operations to execute IMBRange]
 [within address range]
 [return to code]
; start of loop code
.
.
```

---

When writing a self-decompressing program, an IMB must be issued after the routine that decompresses the bulk of the code and before the decompressed code starts to be executed. This is shown in Example 4-3.

#### Example 4-3 Self-decompressing code

---

```
IMB EQU 0xF00000
.
.
; copy and decompress bulk of code
 SVC IMB
; start of decompressed code
.
.
.
```

---

# Chapter 5

## Memory Protection Unit

This chapter describes the *Memory Protection Unit (MPU)* and how it is used. It contains the following sections:

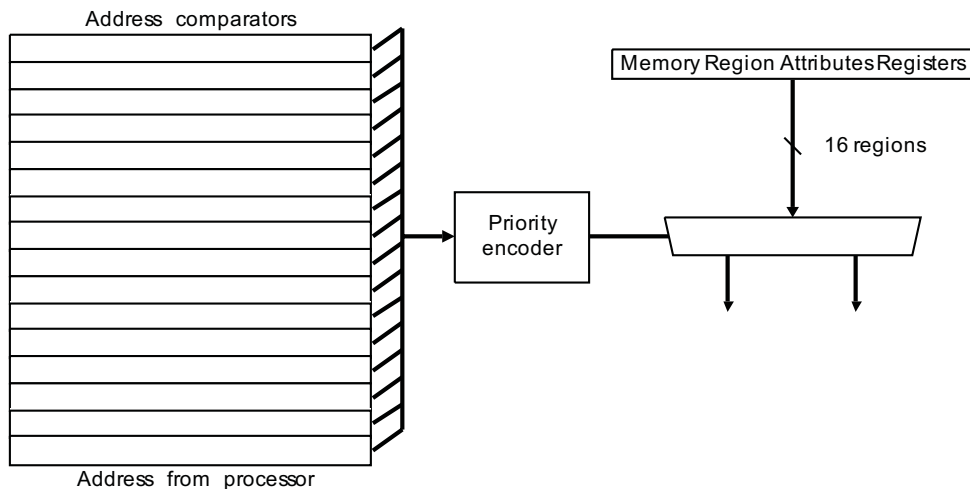

- *About the MPU* on page 5-2
- *Enabling and disabling the MPU* on page 5-7
- *Memory attributes and types* on page 5-10
- *Memory region attributes* on page 5-19
- *Memory access control* on page 5-22
- *MPU aborts* on page 5-23
- *Fault status and address* on page 5-25
- *MPU fault checking* on page 5-27
- *Debug event* on page 5-30.

## 5.1 About the MPU

This section describes how the ARM1156 MPU works.

The MPU supports 16 memory regions. Each region is programmed with a base address and size, and can be overlaid to enable efficient programming of the memory map. To support overlaying the regions are assigned priorities, with region 0 having the lowest priority and region 15 having the highest. The MPU returns access permissions and attributes for the highest priority region in which the address hits.

The MPU enables you to partition memory into regions and set individual protection attributes for each region. You can partition the address space into 16 regions of variable size. Figure 5-1 shows a simplified block diagram of the MPU.

**Figure 5-1 MPU simplified block diagram**

The MPU is programmed using CP15 registers c1 and c6, see *MPU configuration and control* on page 3-6. Memory region control read and write access is permitted only from privileged modes.

### 5.1.1 Memory regions

Before the MPU is enabled, you must program at least one valid protection region. If you do not do this the ARM1156T2F-S processor can enter a state that is recoverable only by reset.

When the MPU is disabled, no access permission checks are performed.

For more details on how to enable or disable the MPU, see *Enabling and disabling the MPU* on page 5-7.

You can partition the address space into a maximum of 16 regions. Each region is specified by the following:

- region base address
- region size
- region attributes
- region access permissions.

The ARM architecture uses constants known as *inline literals* to perform address calculations. These constants are automatically generated by the assembler and compiler and are stored inline with the instruction code. To ensure correct operation, instructions can only be executed from a memory region that has permission for data read access. For more details, see *Memory access control* on page 5-22.

You use CP15 register c6 to specify the:

- base address and region size properties
- region attributes.

### Region base address

The base address defines the start of the memory region. You must align this to a region-sized boundary. For example, if a region size of 8KB is programmed for a given region, the base address must be a multiple of 8KB.

#### ————— Note —————

If the region is not aligned correctly, this results in Unpredictable behavior.

---

### Region size

The region size is specified as a five-bit value, encoding a range of values from 32 Bytes (a cache-line length) to 4GB. The encoding is shown in Table 3-34 on page 3-65.

### Region attributes

Each region has a number of attributes associated with it. These control how a memory access is performed when the processor core issues an address that falls within a given region. The attributes are:

- Memory Type (Strongly ordered, Device, or Normal)
- Shared/Non-Shared
- Non-Cacheable

- Write-through Cacheable
- Write-back Cacheable.

The encoding is shown in Table 5-4 on page 5-19

### Region access permissions

Each region has read/write access permissions for user and privileged modes.

For example, if a User mode application attempts to access a *Privileged mode access only* region a memory abort occurs.

The processor enters the abort exception mode and branches to Data Abort or Prefetch Abort accordingly.

#### 5.1.2 Overlapping regions

You can program the MPU with two or more overlapping regions. When overlapping regions are programmed, a fixed priority scheme is applied to determine the overlapping region attributes that are applied to the memory access. Attributes for region 15 take highest priority, those for region 0 take lowest priority. See *Memory attributes and types* on page 5-10 for more details. For example:

**Region 2**                      Is programmed to be 4KB in size, starting from address 0x3000 with AP [2:0] set to b110. (Privileged mode full access, User mode read-only.)

**Region 1**                      Is programmed to be 16KB in size, starting from address 0x0000 with APn [2:0] set to b101. (Full user mode access only.)

When the processor performs a data write to address 0x3010 while in User mode, the address falls into both region 1 and region 2, as shown in Figure 5-2 on page 5-5. Because there is a clash, the attributes associated with region 2 are applied. Because User mode is read access, only for this region, a Data Abort occurs.

**Figure 5-2 Overlapping memory regions**

### Example of using regions that overlap

Figure 5-3 shows how you can use overlapping regions for stack protection. For example:

- allocate region 1 the appropriate size for all stacks
- allocate region 2 the minimum region size, 32 bytes, by positioning it at the end of the stack for the current process
- Set the region 2 access permissions to No Access.

If the current process overflows the stack it uses, a write access to region 2 by the processor causes the MPU to raise the appropriate fault.

**Figure 5-3 Overlay for stack protection**

### 5.1.3 Background regions

Overlapping regions increase the flexibility of how the regions can be mapped onto physical memory devices in the system. You can also use the overlapping properties to specify a background region. For example, you might have a number of physical memory areas sparsely distributed across the 4GB address space. If a programming error occurs therefore, it might be possible for the processor to issue an address that does not fall into any defined region.

If the address issued by the processor falls outside any of the defined regions, the ARM1156T2F-S MPU is hard-wired to abort the access. You can override this behavior by programming region 0 to be a 4GB background region. In this way, if the address does not fall into any of the other 15 regions, the access is controlled by the attributes and access permissions you have specified for region 0.

## 5.2 Enabling and disabling the MPU

Before the MPU is enabled, you must program at least one valid protection region. If you do not do this the ARM1156T2F-S processor can enter a state that is recoverable only by reset.

When the MPU is disabled, no access permission checks are performed.

You can enable and disable the MPU by writing the M bit, bit 0, of the CP15 Control Register c1. On reset, this bit is cleared to 0, disabling the MPU.

### 5.2.1 Enabling the MPU

Before you enable the MPU you must:

1. Program all relevant CP15 registers. This includes setting up at least one memory region.
2. Clean and invalidate the data cache.
3. Invalidate the instruction caches.

When enabled, the behavior of the MPU is as follows:

- When the Load Store Unit or Prefetch Unit generates a memory access, the MPU compares the memory address with the programmed memory regions.
- If the address does not exist in a memory region, a background fault is signalled to the requesting block, along with status information to enable the Fault Status Register to be correctly formed.
- If a matching memory region is found, then the region information is used:
  1. The access permission bits are used to determine if the access is permitted. If the access is not permitted the MPU signals a memory abort, otherwise the access is permitted to proceed. For more details on access permissions, see *Memory access control* on page 5-22.
  2. The memory region attributes are used to determine if the access is cached, uncached or device and if it is shared, as described in *Memory region attributes* on page 5-19.
- If the address matches in multiple memory regions, then a fixed priority scheme selects the attributes for the highest numbered region.

**Note**

Region 15 is highest priority and region 0 is lowest priority.

### 5.2.2 Disabling the MPU

To disable the MPU:

1. Program all relevant CP15 registers. This includes setting up at least one memory region.
2. Clean the data cache.
3. Invalidate the instruction and data caches.

When the MPU is disabled:

- No memory access permission checks are performed, and no aborts are generated by the MPU.
- Data accesses to the lower 1.5GB of memory are managed as cacheable if the data cache is enabled by setting the C bit (bit 2) of CP15 register c1. Data accesses to the upper 2GB are treated as Noncacheable.
- All instruction accesses to the lower 2GB part of memory are treated as cacheable if the I bit (bit 12) of CP15 register 1 is set to 1. Accesses to the upper 2GB are treated as Noncacheable.
- Program flow prediction functions as normal, controlled by the state of the Z bit (bit 11) of CP15 register 1.
- All MPU and Cache CP15 operations work as normal when the MPU is disabled.
- Instruction and data prefetch operations work as normal. Data prefetch operations have no effect if the data cache is disabled. Instruction prefetch operations have no effect if the instruction cache is disabled.
- Accesses to the TCMs work as normal if one or both TCMs are enabled.
- The outer, or level two, memory attributes are the same as those for the inner, or level one, memory system.

———— **Note** ————

If you change the MPU regions when the MPU is disabled, to prevent data loss, the data cache must be cleaned.

Figure 5-4 on page 5-9 shows the behavior of the memory map to data and instruction accesses and the address ranges when the MPU is disabled. This is also the default behavior of the memory map at reset.

|            | Data access behavior.                                |                                                               | Instruction access behavior.        |                                         |
|------------|------------------------------------------------------|---------------------------------------------------------------|-------------------------------------|-----------------------------------------|
| 0xFFFFFFFF | Strongly Ordered, Shared                             |                                                               | Noncacheable                        |                                         |
| 0xC0000000 |                                                      |                                                               |                                     |                                         |

<sup>†</sup>Can be Not shared if bit [9] of the Auxiliary Control Register is set to 1.

**Figure 5-4 Memory map behavior for data and instruction accesses when MPU is disabled**

5.3 Memory attributes and types

The ARM1156T2F-S processor provides a set of memory attributes that have characteristics that are suited to particular devices, including memory devices, that the memory map can contain. The memory attributes do not define the order that the regions of memory are accessed. There are three mutually exclusive main memory type attributes:

- Strongly Ordered
- Device
- Normal.

These are used to describe the memory regions. A summary of the memory attributes is shown in Table 5-1.

Table 5-1 Memory attributes

| Memory type attribute | Shared/ Non-Shared | Other attributes                                            | Description                                                                                                                                                                                                                                                                                             |
|-----------------------|--------------------|-------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Normal                | Shared             | Noncacheable/ Write-through Cacheable/ Write-back Cacheable | Designed to handle normal memory that is shared between several processors.                                                                                                                                                                                                                             |
|                       | Non-Shared         | Noncacheable/ Write-through Cacheable/ Write-back Cacheable | Designed to handle normal memory that is used only by a single processor.                                                                                                                                                                                                                               |
| Device                | Shared             | -                                                           | Designed to handle memory-mapped peripherals that are shared by several processors.                                                                                                                                                                                                                     |
|                       | Non-Shared         | -                                                           | Designed to handle memory-mapped peripherals that are used only by a single processor.                                                                                                                                                                                                                  |
| Strongly Ordered      | -                  | -                                                           | All memory accesses to Strongly Ordered memory occur in program order. Some backwards compatibility constraints exist with ARMv5 instructions that change the CPSR interrupt masks (see <i>Strongly Ordered memory attribute</i> on page 5-14). All Strongly Ordered accesses are assumed to be shared. |

5.3.1 Normal memory attribute

The Normal memory attribute is defined on a per-region basis in the MPU and provides memory access orderings that are suitable for normal memory. This type of memory stores information without side effects. Normal memory can be writable or read-only.

The behavior for:

- read-only normal memory is:
  - two loads from a specific location return the same data for each load.
- writable normal memory, unless there is a change to the physical address mapping:
  - a load from a specific location returns the most recently stored data at that location for the same processor
  - two loads from a specific location, without a store in between, return the same data for each load.

This behavior describes most memory used in a system. In this section, writable normal memory and read-only normal memory are not distinguished.

Regions of memory with the Normal attribute can be Shared or Non-Shared, on a per-region basis in the MPU.

All explicit accesses to memory marked as Normal must correspond to the ordering requirements of accesses described in *Ordering requirements for memory accesses* on page 5-14. Accesses to Normal memory conform to the Weakly Ordered model of memory ordering. A description of this model is in standard texts describing memory ordering issues.

## Shared Normal memory

The purpose of the Shared Normal memory attribute is to permit normal memory access by multiple processors or other system masters.

A region of memory marked as Shared Normal is one in which the effect of interposing a cache, or caches, on the memory system is entirely transparent. Implementations can use a variety of mechanisms to support this, from not caching accesses in shared regions to more complex hardware schemes for cache coherency for those regions.

ARM1156T2F-S processors do not cache shareable locations at level one.

In systems that implement a TCM, the regions of memory covered by the TCM are always Non-Shared. Marking an area of memory covered by the TCM as being Shared results in Unpredictable behavior.

Writes to Shared Normal memory might not be atomic. That is, all observers might not see the writes occurring at the same time. To preserve coherency where two writes are made to the same location, the order of those writes must be seen to be the same by all observers. Reads to Shared Normal memory that are aligned in memory to the size of the access are atomic.

## Non-Shared Normal memory

The Non-Shared Normal memory attribute describes normal memory that can be accessed only by a single processor.

A region of memory marked as Non-Shared Normal does not have any requirement to make the effect of a cache transparent.

## Cacheable write-through, Cacheable write-back, and Noncacheable

In addition to marking a region of Normal memory as being Shared or Non-Shared, a region of memory marked as Normal can also be marked on a per-region basis in the MPU as being one of:

- Cacheable write-through
- Cacheable write-back
- Noncacheable.

This marking is independent of the marking of a region of memory as being Shared or Non-Shared, and indicates the required handling of the data region for reasons other than those to handle the requirements of shared data. As a result, it is acceptable for a region of memory that is marked as being Cacheable and Shared not to be held in the cache in an implementation that handles Shared regions as not caching the data.

### 5.3.2 Device memory attribute

The Device memory attribute is defined for memory locations where an access to the location can cause side effects, or where the value returned for a load can vary depending on the number of loads performed. Memory-mapped peripherals and I/O locations are typical examples of areas of memory that you must mark as Device. The marking of a region of memory as Device is performed on a per-region basis in the MPU.

Accesses to memory-mapped locations that have side effects that apply to memory of type Normal might require memory barriers to ensure correct execution. An example where this might be an issue is the programming of the control registers of a memory controller while accesses are being made to the memories controlled by the controller.

Instruction fetches must not be performed to areas of memory containing read-sensitive devices, because there is no ordering requirement between instruction fetches and explicit accesses. As a result, instruction fetches from such devices can result in Unpredictable behavior. Up to 64 bytes can be prefetched sequentially ahead of the current instruction being executed. To enable this, you must locate read-sensitive devices in memory in such a way to permit prefetching.

Explicit accesses from the processor to regions of memory marked as Device occur in the size and order defined by the instruction. The number of location accesses is specified by the program. Accesses to regions of memory marked as Device are not restartable. Repeat accesses to such locations when there is only one access in the program are not possible in the ARM1156T2F-S processor. An example of where a repeat access might be required is before and after an interrupt to enable the interrupt to abandon a slow access. These optimizations are not performed on regions of memory marked as Device.

In addition, address locations marked as Device are not held in a cache.

### Shared and non-shared device memory

Regions of memory marked as Device can be characterized by the Shared attribute in the MPU. These memory regions can be marked as:

- Shared Device
- Non-Shared Device.

Explicit accesses to memory with each of the sets of attributes occur in program order relative to other explicit accesses to the same set of attributes.

All explicit accesses to memory marked as Device must correspond to the ordering requirements of accesses described in *Ordering requirements for memory accesses* on page 5-14.

In the ARM1156T2F-S processor Non-Shared Device attribute is assigned to the peripheral Port and Shared Device attribute is assigned to the system bus. This enables predictable access times for local peripherals such as watchdog timers or interrupt controllers.

An example of an implementation where the Shared attribute is used to distinguish memory accesses is an implementation that supports a local bus for its private peripherals, while system peripherals are situated on the main system bus. Such a system can have more predictable access times for local peripherals such as watchdog timers or interrupt controllers.

For Shared Device memory, the data of a write is visible to all observers before the end of a Drain Write Buffer memory barrier. For Non-Shared Device memory, the data of a write is visible to the processor before the end of a Drain Write Buffer memory barrier (see *Explicit memory barriers* on page 5-17).

### 5.3.3 Strongly Ordered memory attribute

Another memory attribute, Strongly Ordered, is defined on a per-region basis in the MPU. Accesses to memory marked as Strongly Ordered have a strong memory-ordering model with respect to all explicit memory accesses from that processor. An access to memory marked as Strongly Ordered acts as a memory barrier to all other explicit accesses from that processor, until the point at which the access is complete (that is, has changed the state of the target location or data has been returned). In addition, an access to memory marked as Strongly Ordered must complete before the end of a memory barrier (see *Explicit memory barriers* on page 5-17).

To maintain backwards compatibility with ARMv5 architecture, any ARMv5 instructions that implicitly or explicitly change the interrupt masks in the CSPR that appear in program order after a Strongly Ordered access must wait for the Strongly Ordered memory access to complete. These instructions are MSR with the control field mask bit set, and the flag setting variants of arithmetic and logical instructions whose destination register is r15, which copies the SPSR to CSPR. This requirement exists only for backwards compatibility with previous versions of the ARM architecture, and the behavior is deprecated in ARMv6. Programs must not rely on this behavior, but instead include an explicit memory barrier (see *Explicit memory barriers* on page 5-17) between the memory access and the following instruction.

The ARM1156T2F-S processor does not require an explicit memory barrier in this situation, but for future compatibility it is recommended that programmers insert a memory barrier.

Explicit accesses from the processor to memory marked as Strongly Ordered occur at their program size, and the number of accesses that occur to such locations is the number that are specified by the program. Accesses to such locations are not repeated when there is only one access in the program. That is, the accesses from the processor to memory marked as Strongly Ordered are not restartable.

Address locations marked as Strongly Ordered are not held in a cache, and are treated as Shared memory locations.

For Strongly Ordered memory, the data and side effects of a write are visible to all observers before the end of a Drain Write Buffer memory barrier (see *Explicit memory barriers* on page 5-17).

### 5.3.4 Ordering requirements for memory accesses

The various memory types defined in this section have restrictions in the memory orderings that are permitted.

## Ordering requirements for two accesses

The order of any two explicit architectural memory accesses where one or more are to memory marked as Non-Shared must obey the ordering requirements shown in Table 5-2. Table 5-2 shows the memory ordering between two explicit accesses A1 and A2, where A1 occurs before A2 in program order.

The symbols used in the table are:

- <      Accesses must occur strictly in program order. That is, A1 must occur strictly before A2. It must be impossible to tell otherwise from observation of the read/write values and side effects caused by the memory accesses.
- ?      Accesses can occur in any order, provided that the requirements of uniprocessor semantics are met, for example respecting dependencies between instructions within a single processor.

**Table 5-2 Memory ordering restrictions**

|    |                           | A2          |                          |                      |                       |                |                           |                       |                        |
|----|---------------------------|-------------|--------------------------|----------------------|-----------------------|----------------|---------------------------|-----------------------|------------------------|
|    |                           | Normal read | Device read (Non-Shared) | Device read (Shared) | Strongly Ordered read | Normal write   | Device write (Non-Shared) | Device write (Shared) | Strongly Ordered write |
| A1 | Normal read               | ?           | ?                        | ?                    | <                     | ? <sup>a</sup> | ?                         | ?                     | <                      |
|    | Device read (Non-Shared)  | ?           | <                        | ?                    | <                     | ?              | <                         | ?                     | <                      |
|    | Device read (Shared)      | ?           | ?                        | <                    | <                     | ?              | ?                         | <                     | <                      |
|    | Strongly Ordered read     | <           | <                        | <                    | <                     | <              | <                         | <                     | <                      |
|    | Normal write              | ?           | ?                        | ?                    | <                     | ?              | ?                         | ?                     | <                      |
|    | Device write (Non-Shared) | ?           | <                        | ?                    | <                     | ?              | <                         | ?                     | <                      |
|    | Device write (Shared)     | ?           | ?                        | <                    | <                     | ?              | ?                         | <                     | <                      |
|    | Strongly Ordered write    | <           | <                        | <                    | <                     | <              | <                         | <                     | <                      |

- a. ARM1156T2F-S processor orders the normal read ahead of normal write.

There are no ordering requirements for implicit accesses to any type of memory.

### Definition of program order of memory accesses

The program order of instruction execution is defined as the order of the instructions in the control flow trace. Two explicit memory accesses in an execution can either be:

**Ordered** Denoted by  $<$ . If the accesses are Ordered, then they must occur strictly in order.

**Weakly Ordered** Denoted by  $\leq$ . If the accesses are Weakly Ordered, then they must occur in order or simultaneously.

The rules for determining this for two accesses A1 and A2 are:

1. If A1 and A2 are generated by two different instructions, then:
  - A1 < A2 if the instruction that generates A1 occurs before the instruction that generates A2 in program order.
  - A2 < A1 if the instruction that generates A2 occurs before the instruction that generates A1 in program order.
2. If A1 and A2 are generated by the same instruction, then:
  - If A1 and A2 are the load and store generated by a SWP or SWPB instruction, then:
    - A1 < A2 if A1 is the load and A2 is the store
    - A2 < A1 if A2 is the load and A1 is the store.
  - If A1 and A2 are two word loads generated by an LDC, LDRD, or LDM instruction, or two word stores generated by an STC, STRD, or STM instruction, but excluding LDM or STM instructions whose register list includes the PC, then:
    - A1  $\leq$  A2 if the address of A1 is less than the address of A2
    - A2  $\leq$  A1 if the address of A2 is less than the address of A1.
  - If A1 and A2 are two word loads generated by an LDM instruction whose register list includes the PC or two word stores generated by an STM instruction whose register list includes the PC, then the program order of the memory operations is not defined.

Multiple load and store instructions (such as LDM, LDRD, STM, and STRD) generate multiple word accesses, each being a separate access to determine ordering.

### 5.3.5 Explicit memory barriers

Two explicit memory barrier operations are described in this section:

- Data Memory Barrier
- Drain Write Buffer.

In addition, to ensure correct operation where the processor writes code, an explicit Flush Prefetch Buffer operation is provided.

These operations are implemented by writing to the CP15 Cache operation register *c7*. For details on how to use this register, see *c7, Cache Operations Register* on page 3-66.

#### Data Memory Barrier

This memory barrier ensures that all explicit memory transactions occurring in program order before this instruction are completed. No explicit memory transactions occurring in program order after this instruction are started until this instruction completes. Other instructions can complete out of order with the Data Memory Barrier instruction.

#### Drain Write Buffer

This memory barrier completes when all explicit memory transactions occurring in program order before this instruction are completed. No explicit memory transactions occurring in program order after this instruction are started until this instruction completes. In fact, no instructions occurring in program order until after the Drain Write Buffer complete.

For Shared memory, the data of a write is visible to all observers before the end of a Drain Write Buffer memory barrier.

For Strongly Ordered memory, the data and the side effects of a write are visible to all observers before the end of a Drain Write Buffer memory barrier.

For Non-Shared memory, the data of a write is visible to the processor before the end of a Drain Write Buffer memory barrier.

#### Flush Prefetch Buffer

The Flush Prefetch Buffer instruction flushes the pipeline in the processor, so that all instructions following the pipeline flush are fetched from memory, including the cache, after the instruction has been completed.

The Flush Prefetch Buffer is guaranteed to perform this function. Alternative methods of performing the same task, such as a branch instruction, can be optimized in the hardware to avoid the pipeline flush, for example, by using a branch predictor.

Combining this with Drain Write Buffer, and potentially invalidating the instruction cache, ensures that any instructions written by the processor are executed.

The execution of a Drain Write Buffer instruction and the invalidation of the instruction cache and Flush Prefetch Buffer is the mechanism that guarantees the correct handling of the self-modifying code.

**Memory synchronization primitives**

Memory synchronization primitives exist to ensure synchronization between different processes, which might be running on the same processor or on different processors. You can use memory synchronization primitives in regions of memory marked as Shared and Non-Shared when the processes to be synchronized are running on the same processor. You must only use them in Shared areas of memory when the processes to be synchronized are running on different processors.

**5.3.6 Backwards compatibility**

The ARMv6 memory attributes are significantly different from those in previous versions of the architecture. Table 5-3 shows the interpretation of the earlier memory types in the light of this definition.

**Table 5-3 Memory region backwards compatibility**

| Previous architectures              | ARMv6 attribute                             |
|-------------------------------------|---------------------------------------------|
| NCNB (Noncacheable, Non Bufferable) | Strongly Ordered <sup>a</sup>               |
| NCB (Noncacheable, Bufferable)      | Shared Device <sup>a</sup>                  |
| Write-through Cacheable, Bufferable | Non-Shared Normal (Write-through cacheable) |
| Write-back Cacheable, Bufferable    | Non-Shared Normal (Write-back Cacheable)    |

a. Memory locations contained within the TCMs are treated as being Noncacheable, rather than Strongly Ordered or Shared Device.

## 5.4 Memory region attributes

Each region has an associated set of memory region attributes. These control:

- accesses to the inner and outer caches
- how the write buffer is used
- if the memory region is shareable and must be kept coherent.

### 5.4.1 C and B bit, and type extension field encodings

The Region Access Control Registers use five bits to encode the memory region type. These are TEX[2:0], and the C and B bits. Table 5-4 shows the mapping of the *Type Extension Field* (TEX) and the Cacheable and Bufferable bits (C and B) to memory region type.

Additionally, the Region Access Control Registers contain the shared bit, S. This bit only applies to Normal, not Device or Strongly Ordered memory, and determines if the memory region is Shared (1), or Non-Shared (0).

**Table 5-4 TEX field, and C and B bit encodings used in Region Access Control Registers**

| Attribute encodings |   |   | Description                                             | Memory type      | Region shareable?       |
|---------------------|---|---|---------------------------------------------------------|------------------|-------------------------|
| TEX                 | C | B |                                                         |                  |                         |
| b000                | 0 | 0 | Strongly Ordered.                                       | Strongly Ordered | Shared <sup>a</sup>     |
| b000                | 0 | 1 | Shared Device.                                          | Device           | Shared <sup>a</sup>     |
| b000                | 1 | 0 | Outer and Inner write-through,<br>No Allocate on Write. | Normal           | s <sup>b</sup>          |
| b000                | 1 | 1 | Outer and Inner write-back,<br>No Allocate on Write.    | Normal           | s <sup>b</sup>          |
| b001                | 0 | 0 | Outer and Inner Noncacheable.                           | Normal           | s <sup>b</sup>          |
| b001                | 0 | 1 | Reserved.                                               | Reserved         | Reserved                |
| b001                | 1 | 0 | Reserved.                                               | Reserved         | Reserved                |
| b001                | 1 | 1 | Reserved                                                | Reserved         | Reserved                |
| b010                | 0 | 0 | Non-Shared Device.                                      | Device           | Non-shared <sup>a</sup> |
| b010                | 0 | 1 | Reserved.                                               | Reserved         | Reserved                |

Table 5-4 TEX field, and C and B bit encodings used in Region Access Control Registers (continued)

| Attribute encodings |   |   | Description                                                                 | Memory type | Region shareable? |
|---------------------|---|---|-----------------------------------------------------------------------------|-------------|-------------------|
| TEX                 | C | B |                                                                             |             |                   |
| 010                 | 1 | X | Reserved.                                                                   | Reserved    | Reserved          |
| 011                 | X | X | Reserved.                                                                   | Reserved    | Reserved          |
| 1BB                 | A | A | Cached memory:<br>BB = Outer policy<br>AA = Inner policy.<br>See Table 5-5. | Normal      | s <sup>b</sup>    |

- a. Shared, regardless of the value of the S bit in the Region Access Control Registers.
- b. s is Shared if the value of the S bit in the Region Access Control Registers is 1, or Non-shared if the value of the S bit is 0.

The Inner and Outer cache policy bits AA (C and B bits) and BB (TEX[1:0]) control the operation of memory accesses to the external memory. Table 5-5 indicates how the MPU and cache interpret the cache policy bits.

Table 5-5 Cache policy bits

| TEX[1:0] (BB)<br>or CB (AA) bits | Cache policy                                             |
|----------------------------------|----------------------------------------------------------|
| b00                              | Noncacheable, Unbuffered.                                |
| b01                              | Write-back cached, Write Allocate, Buffered. Outer only. |
| b10                              | Write-through cached, No Allocate on Write, Buffered.    |
| b11                              | Write-back cached, No Allocate on Write, Buffered.       |

The terms Inner and Outer are applied to levels of caches that can be built in a system. Inner refers to the innermost caches, including level one. Outer refers to the outermost caches. The boundary between Inner and Outer caches is defined in the implementation of a cached system. Inner must always include level one. In a system with three levels of caches, an example is for the Inner attributes to apply to level one and level two, while the Outer attributes apply to level three. In a two-level system, it is envisaged that Inner always applies to level one and Outer to level two.

In ARM1156T2F-S processors, Inner refers to level one and **ACACHE** shows the Outer Cacheable properties. The **ASIDE BAND** signals show the Inner Cacheable values. For an explanation of Strongly Ordered and Device see *Memory attributes and types* on page 5-10.

You can choose which write allocation policy an implementation supports. The Allocate On Write and No Allocate On Write cache policies indicate which allocation policy is preferred for a memory region, but you must not rely on the memory system implementing that policy. ARM1156T2F-S processors do not support Inner Allocate on Write.

Not all Inner and Outer cache policies are mandatory. Table 5-6 gives possible implementation options.

**Table 5-6 Inner and Outer cache policy implementation options**

| Cache policy        | Implementation options                                                                    | Supported by ARM1156T2F-S processors? |
|---------------------|-------------------------------------------------------------------------------------------|---------------------------------------|
| Inner Noncacheable  | Mandatory.                                                                                | Yes                                   |
| Inner write-through | Mandatory.                                                                                | Yes                                   |
| Inner write-back    | Optional. If not supported, the memory system must implement this as Inner write-through. | Yes                                   |
| Outer Noncacheable  | Mandatory.                                                                                | System-dependent                      |
| Outer write-through | Optional. If not supported, the memory system must implement this as Outer Noncacheable.  | System-dependent                      |
| Outer write-back    | Optional. If not supported, the memory system must implement this as Outer write-through. | System-dependent                      |

#### 5.4.2 Shared

This bit indicates that the memory region can be shared by multiple processors. For a full explanation of the Shared attribute see *Memory attributes and types* on page 5-10.

## 5.5 Memory access control

Data and instruction accesses to a memory region are controlled by access permission bits in the Memory Access Control Register.

### 5.5.1 Data access permissions

The access permission bits control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then a permission fault is raised.

The access permissions are determined by the AP[2:0] bits in the Data Access Permission Registers.

Table 5-7 shows the bit values of the AP[2:0] bits that determines the permissions for Privileged and User data access.

**Table 5-7 Access data permission bit encoding**

| AP[2:0] | Privileged permissions | User permissions | Description                                    |
|---------|------------------------|------------------|------------------------------------------------|
| b000    | No access              | No access        | All accesses generate a permission fault       |
| b001    | Read/write             | No access        | Privileged access only                         |
| b010    | Read/write             | Read-only        | Writes in User mode generate permission faults |
| b011    | Read/write             | Read/write       | Full access                                    |
| b100    | UNP                    | UNP              | Reserved                                       |
| b101    | Read-only              | No access        | Privileged read-only                           |
| b110    | Read-only              | Read-only        | Privileged/User read-only                      |
| b111    | UNP                    | UNP              | Reserved                                       |

### 5.5.2 Instruction access permissions

Separate access permissions are supported for instruction accesses. This enables areas of memory to be marked as non-executable, that is contain data only, without affecting data accesses. To execute instructions from a memory region the:

- AP[2:0] bits must be set for data access that are read-only or read/write.
- XN bit must be reset so all instruction fetches are enabled. Table 3-32 on page 3-63 shows the encoding of the instruction access permission bits.

## 5.6 MPU aborts

Mechanisms that can cause the ARM1156T2F-S processor to take an exception because of a memory access are:

- MPU fault**            The MPU detects a restriction and signals the processor.
- Debug Abort**        Monitor debug-mode debug is enabled and a breakpoint or a watchpoint has been detected.
- External abort**      The memory system signals an illegal or faulting memory access.

Collectively these are called *aborts*. Accesses that cause aborts are said to be aborted. If the memory request that aborts is an instruction fetch, a Prefetch Abort exception is raised if and when the processor attempts to execute the instruction corresponding to the aborted access. If the aborted access is a data access or a cache maintenance operation, a Data Abort exception is raised.

All Data Aborts, and aborts caused by cache maintenance operations, cause the *Data Fault Status Register* (DFSR) to be updated so that you can determine the cause of the abort.

For all aborts, excluding imprecise aborts, the *Fault Address Register* (FAR) is updated with the address that caused the abort. External Data Aborts and Parity Aborts can be imprecise and therefore the FAR does not contain the address of the abort. For more details on imprecise Data Aborts, see *Imprecise Data Abort mask in the CPSR/SPSR* on page 2-35.

For the precise value stored in the IFAR see *c6, Instruction Fault Address Register* on page 3-58.

---

### Note

---

The IFAR contains the physical address of the instruction that caused the abort.

---

For instruction aborts the value of r14 is used by the abort handler to determine the address that caused the abort.

### 5.6.1 External aborts

External memory errors are defined as those that occur in the memory system other than those that are detected by an MPU. External memory errors are expected to be extremely rare and are likely to be fatal to the running process. An example of an event that can cause an external memory error is an uncorrectable parity or ECC failure on a level two memory structure.

The presence of a precise external abort is signaled in the Data or Instruction Fault Status Register.

The precise external abort model of VMSAv5 is not supported.

### **External abort on instruction fetch**

Externally generated errors during an instruction prefetch are precise in nature, and are only recognized by the processor if it attempts to execute the instruction fetched from the location that caused the error. The resulting failure is reported in the Instruction Fault Status Register if no higher priority abort (including a Data Abort) has taken place.

The Fault Address Register is not updated on an external abort on instruction fetch.

### **External abort on data read/write**

Externally generated errors during a data read or write can be imprecise. This means that `r14_abt` on entry into the abort handler on such an abort might not hold an address that is related to the instruction that caused the exception. Correspondingly, external aborts can be unrecoverable. See *Aborts* on page 2-33 for more details.

The Fault Address Register is not updated on an imprecise external abort on a data access.

## 5.7 Fault status and address

Table 5-8 shows the encodings that the fault status registers use.

**Table 5-8 Encodings for the fault status registers**

| Priority | Sources                          | FS[12, 10, 3:0] | FAR     |
|----------|----------------------------------|-----------------|---------|
| Highest  | Alignment, data only             | b000001         | Valid   |
|          | Background                       | b000000         | Valid   |
|          | Permission                       | b001101         | Valid   |
|          | Precise External Decoder Abort   | b001000         | Valid   |
|          | Precise External Slave Abort     | b101000         | Valid   |
|          | Imprecise External Decoder Abort | b010110         | Invalid |
|          | Imprecise External Slave Abort   | b110110         | Invalid |
|          | Precise Parity Error Exception   | b011001         | Valid   |
| Lowest   | Imprecise Parity Error Exception | b011000         | Invalid |
|          | Debug Event                      | b000010         | Valid   |

### Note

All other Fault Status encodings are reserved.

A summary of which abort vector is taken, and which of the Fault Status and Fault Address Registers are updated for each abort type is shown in Table 5-9.

**Table 5-9 Summary of aborts**

| Abort Type                   | Abort taken    | Precise? | Register updated? |      |     |      |      |
|------------------------------|----------------|----------|-------------------|------|-----|------|------|
|                              |                |          | IFSR              | DFSR | FAR | WFAR | IFAR |
| Instruction MPU fault        | Prefetch Abort | Yes      | Yes               | No   | No  | No   | Yes  |
| Instruction Debug Abort      | Prefetch Abort | Yes      | Yes               | No   | No  | No   | No   |
| Instruction background fault | Prefetch Abort | Yes      | Yes               | No   | No  | No   | Yes  |
| Instruction External Abort   | Prefetch Abort | Yes      | Yes               | No   | No  | No   | Yes  |

Table 5-9 Summary of aborts (continued)

| Abort Type                     | Abort taken    | Precise? | Register updated? |      |                 |      |      |
|--------------------------------|----------------|----------|-------------------|------|-----------------|------|------|
|                                |                |          | IFSR              | DFSR | FAR             | WFAR | IFAR |
| Instruction cache parity error | Prefetch Abort | Yes      | Yes               | No   | No              | No   | Yes  |
| Data MPU fault                 | Data Abort     | Yes      | No                | Yes  | Yes             | No   | No   |
| Data Debug Abort               | Data Abort     | No       | No                | Yes  | Yes             | Yes  | No   |
| Data background fault          | Data Abort     | Yes      | No                | Yes  | Yes             | No   | No   |
| Data External Abort            | Data Abort     | No       | No                | Yes  | No              | No   | No   |
| Data cache parity error        | Data Abort     | No       | No                | Yes  | No <sup>a</sup> | No   | No   |

- a. The Fault Address Register for data cache parity errors is updated if the parity error occurs during a processor read of the cache memory. Errors generated during cache maintenance and cache clean operations are not required to update the FAR.

## 5.8 MPU fault checking

During the processing of a memory region, the MPU behaves differently because it is checking for faults. The MPU generates three types of fault:

- *Alignment fault* on page 5-28
- *Background fault* on page 5-29
- *Permission fault* on page 5-29.

Aborts that are detected by the MPU are taken before any external memory access takes place.

Alignment fault checking is enabled by the A bit in the Control Register CP15 c1. Alignment fault checking is independent of the MPU being enabled. Access permission faults are only generated when the MPU is enabled.

The access control mechanisms of the MPU detect the conditions that produce these faults. If a fault is detected as the result of a memory access, the MPU aborts the access and signals the fault condition to the processor. Status and address information about faults generated by data accesses are held in DFSR and FAR, see *Fault status and address* on page 5-25. Status information about faults generated by instruction fetches are held in IFSR.

An access violation for a given memory access inhibits any corresponding external access, and an abort is returned to the ARM1156T2F-S processor.

### 5.8.1 Fault checking sequence

Figure 5-5 on page 5-28 shows the fault checking sequence for Memory Attributes Region.

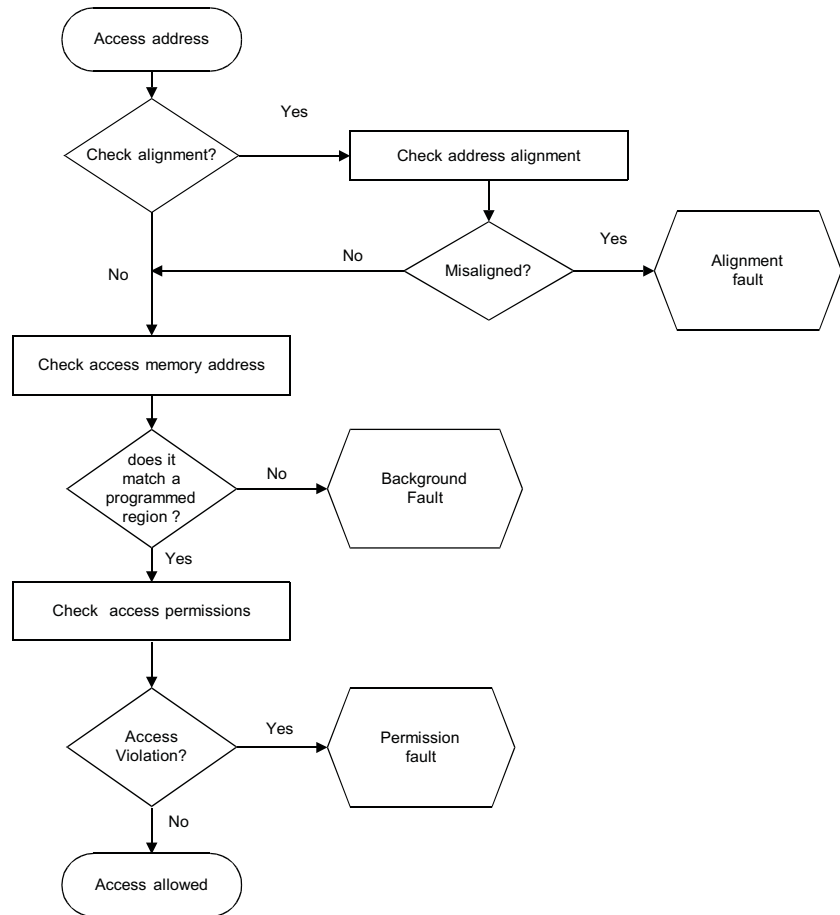

Figure 5-5 Fault checking sequence

### 5.8.2 Alignment fault

An alignment fault occurs if the ARM1156T2F-S processor has attempted to access a particular data memory size at an address location that is not aligned with that size.

For details on conditions for generating Alignment faults, see the *ARM Architecture Reference Manual*.

Alignment checks are performed with the MPU both enabled and disabled.

The alignment fault for doubleword load and store (LDRD, STRD) is strengthened:

- When U is set to 0 to trap if not aligned to an even word address. That is, address bits [2:0]  $\neq 0$ .
- When U is set to 1 to trap if not aligned to a word boundary, That is, address bits [1:0]  $\neq 0$ .

### 5.8.3 Background fault

If the memory access address does not match one of the programmed memory regions, a background fault is generated.

### 5.8.4 Permission fault

The access permissions as defined in Memory Access Control are checked against the processor memory access. If the access is not enabled, an abort is signaled to the processor.

## 5.9 Debug event

When Monitor debug-mode debug is enabled an abort can be taken caused by a breakpoint on an instruction access or a watchpoint on a data access. In both cases the memory system completes the access before the abort is taken. If an abort is taken when in Monitor debug-mode debug then the appropriate FSR (IFSR or DFSR) is updated to indicate a Debug Abort.

If a watchpoint is taken the WFAR is set to the address that caused the watchpoint. Watchpoints are not taken precisely because following instructions can run underneath load and store multiples. The debugger must read the WFAR to determine which instruction caused the debug event.

# Chapter 6

## Unaligned and Mixed-Endian Data Access Support

This chapter describes the unaligned and mixed-endianness data access support for the ARM1156T2F-S processor. It contains the following sections:

- *About unaligned and mixed-endian support* on page 6-2
- *Unaligned access support* on page 6-3
- *Unaligned data access specification* on page 6-7
- *Operation of unaligned accesses* on page 6-18
- *Mixed-endian access support* on page 6-22
- *Instructions to reverse bytes in a general-purpose register* on page 6-29
- *Instructions to change the CPSR E bit* on page 6-30.

## 6.1 About unaligned and mixed-endian support

The ARM1156T2F-S processor executes the ARM architecture v6 instructions that support mixed-endian access in hardware, and assist unaligned data accesses. The extensions to ARMv6 that support unaligned and mixed-endian accesses include the following:

- CP15 register c1 has a U bit that enables unaligned support. This bit was specified as zero in previous architectures, and resets to zero for backwards compatibility.
- Architecturally defined unaligned word and halfword access specification for hardware implementation.
- Byte reverse instructions that operate on general-purpose register contents to support signed or unsigned halfword data values.
- Separate instruction and data endianness, with instructions fixed as little-endian format, naturally aligned, but with support for 32-bit word-invariant binary images and ROM.
- A PSR endian control flag, the E bit, cleared on reset and exception entry, that adds a byte-reverse operation to all entire instructions that read or write memory as data is loaded into and stored back out of the register file. In previous architectures this Program Status Register bit was specified as zero. It is not set in code written to conform to architectures before ARMv6.
- ARM and Thumb instructions to set and clear the E bit explicitly.
- A byte-invariant addressing scheme to support fine-grain big-endian and little-endian shared data structures, to conform to a shared memory standard.

The original ARM architecture was designed as little-endian. This provides a consistent address ordering of bits, bytes, words, cache lines, and pages, and is assumed by the documentation of instruction set encoding and memory and register bit significance. Subsequently, big-endian support was added to enable big-endian byte addressing of memory. A little-endian nomenclature is used for bit-ordering and byte addressing throughout this manual.

## 6.2 Unaligned access support

Instructions must always be aligned as follows:

- ARM 32-bit instructions must be word boundary aligned (Address [1:0] = b00)
- Thumb instructions must be halfword boundary aligned (Address [0] = 0).

Unaligned data access support is described in:

- *Word-invariant mode support*
- *ARMv6 extensions*
- *Word-invariant mode and ARMv6 configurations* on page 6-4
- *Word-invariant data access in ARMv6 (U=0)* on page 6-4
- *Support for unaligned data access in ARMv6 (U=1)* on page 6-5
- *ARMv6 unaligned data access restrictions* on page 6-5.

### 6.2.1 Word-invariant mode support

For ARM architectures prior to ARM architecture v6, data access to non-aligned word and halfword data was treated as aligned from the memory interface perspective. That is, the address is treated as truncated with Address[1:0] treated as zero for word accesses, and Address[0] treated as zero for halfword accesses.

Load single word ARM instructions are also architecturally defined to rotate right the word aligned data transferred by a non word-aligned access. See the *ARM Architecture Reference Manual*.

Alignment fault checking is specified for processors with architecturally compliant *Memory Protection Units* (MPUs), under control of CP15 Register c1 A bit, bit 1. When a transfer is not naturally aligned to the size of data transferred, a Data Abort is signaled with an Alignment fault status code. See the *ARM Architecture Reference Manual* for more details.

### 6.2.2 ARMv6 extensions

ARMv6 adds unaligned word and halfword load and store data access support. When enabled, one or more memory accesses are used to generate the required transfer of adjacent bytes transparently, apart from a potentially greater access time where the transaction crosses a word-boundary.

#### ———— Note ————

The memory management specification defines a programmable mechanism to enable unaligned access support. This is controlled and programmed using the CP15 register c1 U bit, bit 22.

Non word-aligned accesses for load and store multiple/double, semaphore, synchronization, and coprocessor accesses always signal Data Abort with an Alignment fault status code when the U bit is set.

Strict alignment checking is also supported in ARMv6, under control of the CP15 register c1 A bit (bit 1) and signals a Data Abort with an Alignment fault status code if a 16-bit access is not halfword aligned or a single 32-bit load/store transfer is not word aligned.

ARMv6 alignment fault detection is a mandatory function associated with address generation rather than optionally supported in external memory management hardware.

6.2.3 Word-invariant mode and ARMv6 configurations

The unaligned access handling is summarized in Table 6-1.

Table 6-1 Unaligned access handling

| CP15 register c1 U bit | CP15 register c1 A bit | Unaligned access model                                                       |
|------------------------|------------------------|------------------------------------------------------------------------------|
| 0 <sup>a</sup>         | 0 <sup>a</sup>         | Word-invariant ARMv5. See <i>Word-invariant data access in ARMv6 (U=0)</i> . |
| 0                      | 1                      | Word-invariant natural alignment check.                                      |
| 1                      | 0                      | ARMv6 unaligned half/word access, else strict word alignment check.          |
| 1                      | 1                      | ARMv6 strict half/word alignment check.                                      |

a. Default value at reset.

For a fuller description of the options available, see *c1, Control Register* on page 3-46.

6.2.4 Word-invariant data access in ARMv6 (U=0)

The ARM1156T2F-S processor emulates earlier architecture unaligned accesses to memory as follows:

- If A bit is asserted alignment faults occur for:  
**Halfword access**    Address[0] is 1.  
**Word access**        Address[1:0] is not b00.  
**LDRD or STRD**      Address [2:0] is not b000.  
**Multiple access**    Address [1:0] is not b00.

- If alignment faults are enabled and the access is not aligned then the Data Abort vector is entered with an Alignment fault status code.
- If no alignment fault is enabled, that is, if bit 1 of CP15 register c1, the A bit, is not set:

- |                        |                                                                    |
|------------------------|--------------------------------------------------------------------|
| <b>Byte access</b>     | Memory interface uses full Address [31:0].                         |
| <b>Halfword access</b> | Memory interface uses Address [31:1]. Address [0] asserted as 0.   |
| <b>Word access</b>     | Memory interface uses Address [31:2]. Address [1:0] asserted as 0. |
- ARM load data rotates the aligned read data and rotates this right by the byte-offset denoted by Address [1:0], see the *ARM Architecture Reference Manual*.
  - ARM and Thumb load-multiple accesses always treated as aligned. No rotation of read data.
  - ARM and Thumb store word and store multiple treated as aligned. No rotation of write data.
  - ARM load and store doubleword operations treated as 64-bit aligned.
  - Thumb load word data operations are Unpredictable if not word aligned.
  - ARM and Thumb halfword data accesses are Unpredictable if not halfword aligned.

### 6.2.5 Support for unaligned data access in ARMv6 (U=1)

The ARM1156T2F-S processor memory interfaces can generate unaligned low order byte address offsets only for halfword and single word load and store operations, and byte accesses unless the A bit is set. These accesses produce an alignment fault if the A bit is set, and for some of the cases described in *ARMv6 unaligned data access restrictions*.

If alignment faults are enabled and the access is not aligned then the Data Abort vector is entered with an Alignment Fault status code.

### 6.2.6 ARMv6 unaligned data access restrictions

The following restrictions apply for ARMv6 unaligned data access:

- Accesses are not guaranteed atomic. They might be synthesized out of a series of aligned operations in a shared memory system without guaranteeing locked transaction cycles.
- Unaligned accesses loading the PC produce an alignment trap.

- Accesses typically take a number of cycles to complete compared to a naturally aligned transfer. The real-time implications must be carefully analyzed and key data structures might require to have their alignment adjusted for optimum performance.
- Accesses can abort on either or both halves of an access where this occurs over a memory region boundary. The Data Abort handler must handle restartable aborts carefully after an Alignment fault status code is signaled.

As a result, shared memory schemes must not rely on seeing monotonic updates of non-aligned data of loads, stores, and swaps for data items greater than byte width. Unaligned access operations must not be used for accessing Device memory-mapped registers, and must be used with care in Shared memory structures that are protected by aligned semaphores or synchronization variables.

An Alignment fault occurs if unaligned accesses to Strongly Ordered or Device memory are attempted regardless of the setting of the A bit.

Swap and synchronization primitives, multiple-word or coprocessor access produce an alignment fault regardless of the setting of the A bit.

## 6.3 Unaligned data access specification

The architectural specification of unaligned data representations is defined in terms of bytes transferred between memory and register, regardless of bus width and bus endianness.

Little-endian data items are described using lower-case byte labeling bX...b0 (byte X to byte 0) and a pointer is always treated as pointing to the least significant byte of the addressed data.

Big-endian data items are described using upper-case byte labeling B0...BX (BYTE0 to BYTEX) and a pointer is always treated as pointing to the most significant byte of the addressed data.

### 6.3.1 Load unsigned byte, endian independent

The addressed byte is loaded from memory into the low eight bits of the general-purpose register and the upper 24 bits are zeroed (Figure 6-1).

Figure 6-1 Load unsigned byte

### 6.3.2 Load signed byte, endian independent

The addressed byte is loaded from the memory into the low eight bits of the general-purpose register and the sign bit is extended into the upper 24 bits of the register (Figure 6-2 on page 6-8).

Figure 6-2 Load signed byte

In Figure 6-2, se means b (bit 7) sign extension.

6.3.3 Store byte, endian independent

The low eight bits of the general-purpose register are stored into the addressed byte in memory (Figure 6-3).

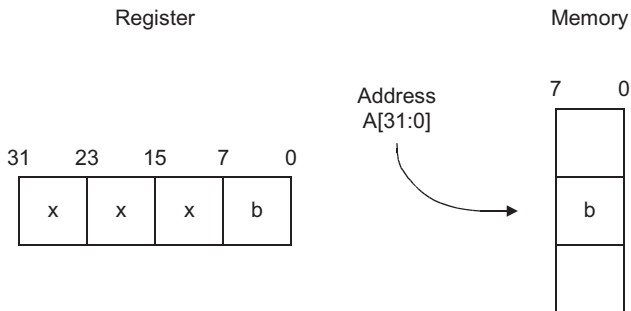

Figure 6-3 Store byte

6.3.4 Load unsigned halfword, little-endian

The addressed byte-pair is loaded from memory into the low 16 bits of the general-purpose register, and the upper 16 bits are zeroed so that the least-significant addressed byte in memory appears in bits [7:0] of the ARM register (Figure 6-4 on page 6-9).

**Figure 6-4 Load unsigned halfword, little-endian**

If strict alignment fault checking is enabled and Address bit 0 is not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.

### 6.3.5 Load unsigned halfword, big-endian

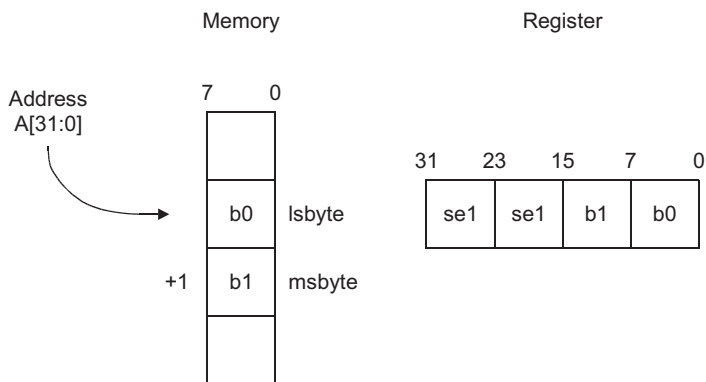

The addressed byte-pair is loaded from memory into the low 16 bits of the general-purpose register, and the upper 16 bits are zeroed so that the most-significant addressed byte in memory appears in bits [15:8] of the ARM register (Figure 6-5).

**Figure 6-5 Load unsigned halfword, big-endian**

If strict alignment fault checking is enabled and Address bit 0 is not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.

### 6.3.6 Load signed halfword, little-endian

The addressed byte-pair is loaded from memory into the low 16-bits of the general-purpose register, so that the least-significant addressed byte in memory appears in bits [7:0] of the ARM register and the upper 16 bits are sign-extended from bit 15 (Figure 6-6).

**Figure 6-6 Load signed halfword, little-endian**

In Figure 6-6, se1 means bit 15 (b1 bit 7) sign extended.

If strict alignment fault checking is enabled and Address bit 0 is not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.

### 6.3.7 Load signed halfword, big-endian

The addressed byte-pair is loaded from memory into the low 16-bits of the general-purpose register, so that the most significant addressed byte in memory appears in bits [15:8] of the ARM register and bits [31:16] replicate the sign bit in bit 15 (Figure 6-7 on page 6-11).

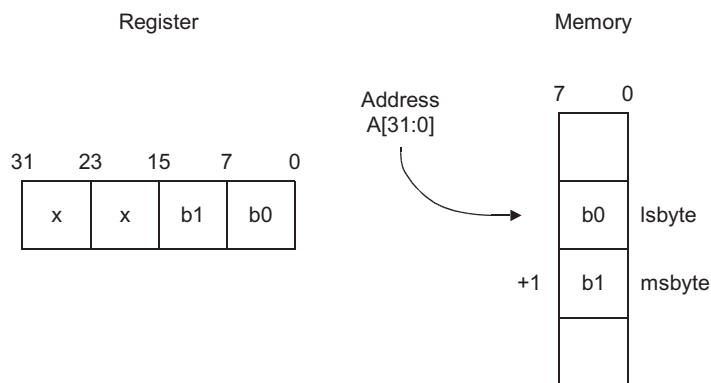

**Figure 6-7 Load signed halfword, big-endian**

In Figure 6-7, SE0 means bit 15 (B0 bit 7) sign extended.

If strict alignment fault checking is enabled and Address bit 0 is not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.

### 6.3.8 Store halfword, little-endian

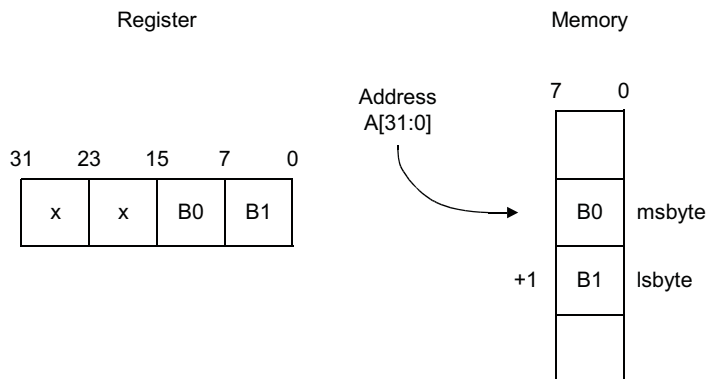

The low 16 bits of the general-purpose register are stored into the memory with bits [7:0] written to the addressed byte in memory, bits [15:8] to the incremental byte address in memory (Figure 6-8).

**Figure 6-8 Store halfword, little-endian**

If strict alignment fault checking is enabled and Address bit 0 is not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.

### 6.3.9 Store halfword, big-endian

The low 16 bits of the general-purpose register are stored into the memory with bits [15:8] written to the addressed byte in memory, bits [7:0] to the incremental byte address in memory (Figure 6-9).

**Figure 6-9 Store halfword, big-endian**

If strict alignment fault checking is enabled and Address bits [1:0] is not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.

### 6.3.10 Load word, little-endian

The addressed byte-quad is loaded from memory into the 32-bit general-purpose register so that the least-significant addressed byte in memory appears in bits [7:0] of the ARM register (Figure 6-10 on page 6-13).

**Figure 6-10 Load word, little-endian**

If strict alignment fault checking is enabled and Address bits [1:0] is not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.

### 6.3.11 Load word, big-endian

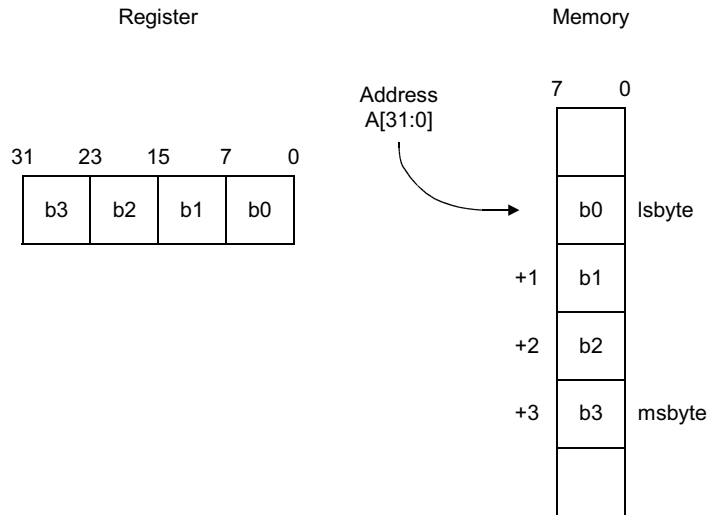

The addressed byte-quad is loaded from memory into the 32-bit general-purpose register so that the most significant addressed byte in memory appears in bits [31:24] of the ARM register (Figure 6-11 on page 6-14).

**Figure 6-11 Load word, big-endian**

If strict alignment fault checking is enabled and Address bits [1:0] is not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.

### 6.3.12 Store word, little-endian

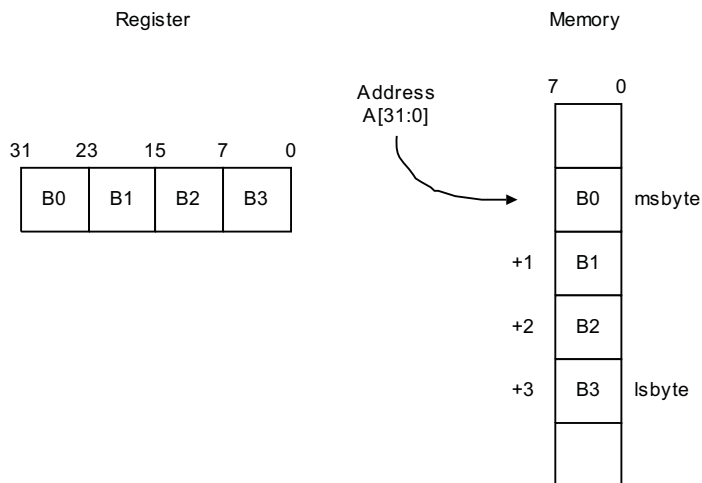

The 32-bit general-purpose register is stored to four bytes in memory where bits [7:0] of the ARM register are transferred to the least-significant addressed byte in memory (Figure 6-12 on page 6-15).

**Figure 6-12 Store word, little-endian**

If strict alignment fault checking is enabled and Address bits [1:0] are not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.

### 6.3.13 Store word, big-endian

The 32-bit general-purpose register is stored to four bytes in memory where bits [31:24] of the ARM register are transferred to the most-significant addressed byte in memory. Figure 6-13 on page 6-16 show this.

**Figure 6-13 Store word, big-endian**

If strict alignment fault checking is enabled and Address bits [1:0] are not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.

### 6.3.14 Load double, load multiple, load coprocessor (little-endian, E = 0)

The access is treated as a series of incrementing aligned word loads from memory. The data is treated as load word data (see *Load word, little-endian* on page 6-13) where:

- The lowest two address bits are zeroed for load multiple, load coprocessor. If strict alignment fault checking is enabled and effective Address bits [1:0] are not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.
- The lowest three address bits are zeroed for load double. If strict alignment fault checking is enabled and effective Address bits [2:0] are not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.

### 6.3.15 Load double, load multiple, load coprocessor (big-endian, E=1)

The access is treated as a series of incrementing aligned word loads from memory. The data is treated as load word data (see *Load word, big-endian* on page 6-14) where:

- The lowest two address bits are zeroed for load multiple, load coprocessor. If strict alignment fault checking is enabled and effective Address bits [1:0] are not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.
- The lowest three address bits are zeroed for load double. If strict alignment fault checking is enabled and effective Address bits [2:0] are not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.

### 6.3.16 Store double, store multiple, store coprocessor (little-endian, E=0)

The access is treated as a series of incrementing aligned word stores to memory. The data is treated as store word data (see *Store word, little-endian* on page 6-15) where:

- The lowest two address bits are zeroed for load multiple, load coprocessor. If strict alignment fault checking is enabled and effective Address bits [1:0] are not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.
- The lowest three address bits are zeroed for load double. If strict alignment fault checking is enabled and effective Address bits [2:0] are not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.

### 6.3.17 Store double, store multiple, store coprocessor (big-endian, E=1)

The access is treated as a series of incrementing aligned word stores to memory. The data is treated as store word data (see *Store word, big-endian* on page 6-16) where:

- The lowest two address bits are zeroed for load multiple, load coprocessor. If strict alignment fault checking is enabled and effective Address bits [1:0] are not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.
- The lowest three address bits are zeroed for load double. If strict alignment fault checking is enabled and effective Address bits [2:0] are not zero, then a Data Abort is generated and the MPU returns an Alignment fault in the Fault Status Register.

## 6.4 Operation of unaligned accesses

Alignment faults and the operation of non-faulting accesses of the ARM1156T2F-S processor are described in this section.

Table 6-3 on page 6-19 gives details of when an Alignment fault must occur for an access and of when the behavior of an access is architecturally Unpredictable. When an access neither generates an Alignment fault and is not Unpredictable, details of precisely which memory locations are accessed are also given in the table.

The access type descriptions used in the Table 6-3 on page 6-19 are determined from the load/store instruction given in Table 6-2.

Table 6-2 Access type descriptions

| Access type | ARM instructions                                      | Thumb instructions      | Thumb-2 instructions            |
|-------------|-------------------------------------------------------|-------------------------|---------------------------------|
| Byte        | LDRB, LDRBT, LDRSB, STRB, STRBT, SWPB (either access) | LDRB, LDRSB, STRB       | LDRB, LDRBT, LDRSB, STRB, STRBT |
| Halfword    | LDRH, LDRSH, LDRHT, STRH                              | LDRH, LDRSH, STRH       | LDRH, LDRSH, STRH               |
| WLoad       | LDR, LDRT, SWP (load access, if U is set to 0)        | LDR                     | LDR, LDRT                       |
| WStore      | STR, STRT, SWP (store access, if U is set to 0)       | STR                     | STR, STRT,                      |
| WSync       | LDREX, STREX, SWP (either access, if U is set to 1)   | ---                     | LDREX, STREX                    |
| Two-word    | LDRD, STRD                                            | ---                     | LDRD, STRD                      |
| Multi-word  | LDC, LDM, RFE, SRS, STC, STM                          | LDMIA, POP, PUSH, STMIA | LDC, LDM, RFE, SRS, STC, STM    |

The following terminology is used to describe the memory locations accessed:

**Byte[X]** This means the byte whose address is X in the current endianness model. The correspondence between the endianness models is that Byte[A] in the LE endianness model, Byte[A] in the BE-8 endianness model, and Byte[A EOR 3] in the BE-32 endianness model are the same actual byte of memory.

**Halfword[X]**

This means the halfword consisting of the bytes whose addresses are X and X+1 in the current endianness model, combined to form a halfword in little-endian order in the LE endianness model or in big-endian order in the BE-8 or BE-32 endianness model.

**Word[X]**

This means the word consisting of the bytes whose addresses are X, X+1, X+2, and X+3 in the current endianness model, combined to form a word in little-endian order in the LE endianness model or in big-endian order in the BE-8 or BE-32 endianness model.

**Note**

It is a consequence of these definitions that if X is word-aligned, Word[X] consists of the same four bytes of actual memory in the same order in the LE and BE-32 endianness models.

**Align(X)**

This means X AND 0xFFFFF0. That is, X with its least significant two bits forced to zero to make it word-aligned.

There is no difference between Addr and Align(Addr) on lines where Addr[1:0] is set to b00. You can use this to simplify the control of when the least significant bits are forced to zero.

For the Two-word and Multi-word access types, the memory accessed column only specifies the lowest word accessed. Subsequent words have addresses constructed by successively incrementing the address of the lowest word by four, and are constructed using the same endianness model as the lowest word.

**Table 6-3 Alignment fault occurrence when access behavior is architecturally unpredictable**

| <b>A</b> | <b>U</b> | <b>Addr [2:0]</b> | <b>Access type(s)</b> | <b>Behavior</b> | <b>Memory accessed</b> | <b>Notes</b>                                    |
|----------|----------|-------------------|-----------------------|-----------------|------------------------|-------------------------------------------------|
| 0        | 0        | -                 | -                     | -               | -                      | Word-invariant, no alignment faulting           |
| 0        | 0        | bxxx              | Byte                  | Normal          | Byte[Addr]             | -                                               |
| 0        | 0        | bxx0              | Halfword              | Normal          | Halfword[Addr]         | -                                               |
| 0        | 0        | bxx1              | Halfword              | Unpredictable   | -                      | -                                               |
| 0        | 0        | bxxx              | WLoad                 | Normal          | Word[Align(Addr)]      | Loaded data rotated right by 8 * Addr[1:0] bits |
| 0        | 0        | bxxx              | WStore                | Normal          | Word[Align(Addr)]      | Operation unaffected by Addr[1:0]               |
| 0        | 0        | bx00              | WSync                 | Normal          | Word[Addr]             | -                                               |

**Table 6-3 Alignment fault occurrence when access behavior is architecturally unpredictable (continued)**

| <b>A</b> | <b>U</b> | <b>Addr [2:0]</b> | <b>Access type(s)</b>            | <b>Behavior</b>     | <b>Memory accessed</b> | <b>Notes</b>                      |

| 1        | x        | b000              | Two-word                         | Normal              | Word[Addr]             |                                   |

**Table 6-3 Alignment fault occurrence when access behavior is architecturally unpredictable (continued)**

| A | U | Addr [2:0] | Access type(s) | Behavior        | Memory accessed | Notes                                     |
|---|---|------------|----------------|-----------------|-----------------|-------------------------------------------|
| 1 | 0 | b100       | Two-word       | Alignment Fault |                 | U set to 0: 64-bit alignment of LDRD/STRD |
| 1 | 1 | b100       | Two-word       | Normal          | Word[Addr]      | U set to 1: 32-bit alignment of LDRD/STRD |
| 1 | x | bxx1, bx1x | Two-word       | Alignment Fault | -               | -                                         |

- a. Alignment faults occur when accesses using Addr[1:0] of b1x or bx1 are made to Strongly Ordered or Device memory with U bit set.

The following causes override the behavior specified in the Table 6-3 on page 6-19:

- An LDR instruction that loads the PC, has Addr[1:0] != b00, and is specified in the table as having Normal behavior instead has Unpredictable behavior.  
The reason why this applies only to LDR is that most other load instructions are Unpredictable regardless of alignment if the PC is specified as their destination register.  
The exceptions are the ARM LDM and RFE instructions, and the Thumb POP instruction. If the instruction for them is Addr[1:0] != b00, the effective address of the transfer has its two least significant bits forced to 0 if A is set 0 and U is set to 0. Otherwise the behavior specified in *Alignment fault occurrence when access behavior is architecturally unpredictable* on page 6-19 is either Unpredictable or an Alignment fault regardless of the destination register.
- Any WLoad, WStore, WSync, Two-word, or Multi-word instruction that accesses device memory, has Addr[1:0] != b00, and is specified in *Alignment fault occurrence when access behavior is architecturally unpredictable* on page 6-19 as having Normal behavior instead has Unpredictable behavior.
- Any Halfword instruction that accesses device memory, has Addr[0] != 0, and is specified in the table as having Normal behavior instead has Unpredictable behavior.

## 6.5 Mixed-endian access support

Mixed-endian data access is described in:

- *Word-invariant fixed instruction and data endianness* on page 6-24
- *ARMv6 support for mixed-endian data* on page 6-25
- *Instructions to change the CPSR E bit* on page 6-30.

### 6.5.1 Differences between BE-32 and BE-8 buses

The differences between handling Word-Invariant, or BE-32, and Byte-Invariant, or BE-8, data buses are:

- In a BE-32, Word-Invariant, system, the representation of a 32-bit Word access is the same between a BE-32 access and a LE access to the same word address. However, the representation of the byte (and half-word) accesses on the bus is different.
- In a BE-8, Byte Invariant, system the representation of a byte access is the same between a BE-8 access and a LE access to the same byte address. However, the representation of the word (and half-word) accesses on the bus is different.

In BE-32 and BE-8 implementations of big-endian access, the lowest byte address corresponds to the most significant byte

Table 6-4 on page 6-23 shows:

- the effect of LE, BE-8 and BE-32 accesses on a 64 bit wide bus.
- the basic form that for Byte accesses, LE and BE-8 columns are the same, and for Word accesses LE and BE-32 columns are the same.

---

**Note**

In both the BE-8 and the BE-32 cases, the byte access to address 0 (the lowest address) corresponds to the most significant byte of the word access, so fitting the big-endian description.

---

Table 6-4 Byte lanes used for LE, BE-8 and BE-32 accesses

| Data Bus Pins | Byte Accesses |      |       | Halfword Accesses |       |       | Word Accesses |         |         |
|---------------|---------------|------|-------|-------------------|-------|-------|---------------|---------|---------|
|               | LE            | BE-8 | BE-32 | LE                | BE-8  | BE-32 | LE            | BE-8    | BE-32   |
| 63:56         | A7            | A7   | A4    | A6:MS             | A6:LS | A4:MS | A4:MS         | A4:LS   | A4:MS   |
| 55:48         | A6            | A6   | A5    | A6:LS             | A6:MS | A4:LS | A4:MS-1       | A4:LS+1 | A4:MS-1 |
| 47:40         | A5            | A5   | A6    | A4:MS             | A4:LS | A6:MS | A4:LS+1       | A4:MS-1 | A4:LS+1 |
| 39:32         | A4            | A4   | A7    | A4:LS             | A4:MS | A6:LS | A4:LS         | A4:MS   | A4:LS   |
| 31:24         | A3            | A3   | A0    | A2:MS             | A2:LS | A0:MS | A0:MS         | A0:LS   | A0:MS   |
| 23:16         | A2            | A2   | A1    | A2:LS             | A2:MS | A0:LS | A0:MS-1       | A0:LS+1 | A0:MS-1 |
| 15:8          | A1            | A1   | A2    | A0:MS             | A0:LS | A2:MS | A0:LS+1       | A0:MS-1 | A0:LS+1 |
| 7:0           | A0            | A0   | A3    | A0:LS             | A0:MS | A2:LS | A0:LS         | A0:MS   | A0:LS   |

Key to Table 6-4:

**A<Num>** Byte access to address[2:0] = Num

**A<Num>:<Byte>** Byte <Byte> of Word/Half-word access to address[2:0]=Num

**<Byte> : MS** Most significant byte

**MS-1** Second most significant byte

**LS+1** Second least significant byte

**LS** Least significant byte

## 6.5.2 Interaction between the Bus protocol and the core endianness

The ARM architecture supports two forms of handling big-endian accesses. The original (legacy) support is based around the BE-32 implementation of big-endian accesses for both instruction and data accesses, and is controlled by the CP15 Register 1 B bit.

The ARMv6 architecture supports BE-8 implementation of data accesses only under control of the CPSR E bit. The value on exception entry of the CPSR E bit is handled by the CP15 Register 1 EE bit. In addition, the CP15 B bit is supported for pre-ARMv6 architectures.

Table 6-6 on page 6-25 summarizes the effect of the E and B bits on instruction and data endianness.

**Table 6-5 Effect on E and B bits on instruction and data endianness**

| E bit (CPSR) | B bit (CP15 register1) | Instruction Endianness | Data Endianness |
|--------------|------------------------|------------------------|-----------------|
| 0            | 0                      | LE                     | LE              |
| 0            | 1                      | BE-32                  | BE-32           |
| 1            | 0                      | LE                     | BE-8            |
| 1            | 1                      | Unpredictable          | Unpredictable   |

In addition, the value of the B bit and the EE bit at reset are determined on ARM cores by the setting of hardware configuration bits. This enables you to configure a system in a particular way from reset.

The distinction between BE-8 and BE-32 is visible to the programmer in its interactions with peripherals, ROMs and regions of RAM that are accessed by other cores or debuggers. In the case of peripherals (and ROMs), the visibility arises from the connectivity between the peripheral (or ROM) and the bus. In the case of debuggers, the visibility arises from the danger of different endian implementations between the different debuggers.

Therefore, if a peripheral returns only word data, then the peripheral only supports word accesses. The connection between the bus and the peripheral is different if the bus is BE-8, or if the bus is BE-32, and for the LE bus, the connection is the same as the BE-32 bus. Equally, a peripheral might return only byte data. In that case the connection between the bus and the peripheral is different if the bus is BE-32 or if the bus is BE-8, and for the LE bus, the connection is the same as the BE-8 bus.

The conversion mechanism between BE-32 and BE-8, enables the required BE-32 accesses from the B bit, as shown in Table 6-5, to be converted to BE-8 accesses. This enables an AXI bus, which has no support for BE-32 accesses, to be connected to a system that performs BE-8 accesses. As a result, the use of AXI on an ARM core is compatible with having the B bit set to 1.

**6.5.3 Word-invariant fixed instruction and data endianness**

Prior to ARMv6 the endianness of both instructions and data are locked together, and the configuration of the processor and the external memory system must either be hard-wired or programmed in the first few instructions of the bootstrap code.

Where the endianness is configurable under program control, the MPU provides a mechanism in CP15 c1 to set the B bit. This enables byte addressing renaming with 32-bit words. The BE-32 model of big-endian access relies on a word-invariant view of memory where an aligned 32-bit word reads and writes the same word of data in memory when configured as either big-endian or little-endian. This enables an ARM 32-bit instruction sequence to be executed to program the B bit, but no byte or halfword data accesses or 16-bit Thumb instructions can be used until the processor configuration matches the system endianness.

This behavior is still provided for software when the U bit in CP15 Register c1 is zero (Table 6-6).

**Table 6-6 Word-invariant endianness using CP15 c1**

| U | B | Instruction endianness | Data endianness | Description                |
|---|---|------------------------|-----------------|----------------------------|
| 0 | 0 | LE                     | LE              | LE (reset condition)       |
| 0 | 1 | BE-32                  | BE-32           | BE (32-bit word-invariant) |

#### 6.5.4 ARMv6 support for mixed-endian data

In ARMv6 the instruction and data endianness are separated:

- instructions are fixed little-endian
- data accesses can be either little-endian or big-endian as controlled by bit 9, the E bit, of the Program Status Register.

The value of the E bit on any exception entry, including reset, is determined by the CP15 Control Register EE bit.

##### Fixed little-endian instructions

Instructions must be naturally aligned and are always treated as being stored in memory in little-endian format. That is, the PC points to the *least-significant-byte* (LSB) of the instruction.

Instructions have to be treated as data by exception handlers. For example, decoding SVC calls and Undefined instructions.

Instructions can also be written as data by debuggers, Just-In-Time compilers, or in operating systems that update exception vectors.

## Mixed-endian data access

The operating system typically has a required endian representation of internal data structures, but applications and device drivers have to work with data shared with other processors (DSP interfaces) that might have fixed big-endian or little-endian data formatting.

A byte-invariant addressing mechanism is provided that enables the load/store architecture to be qualified by the CPSR E bit that provides byte reversing of big-endian data in to, and out of, the processor register bank transparently. This byte-invariant big-endian representation is called BE-8 in this document.

The effect on byte, halfword, word, and multi-word accesses of setting the CPSR E bit when the U bit enables unaligned support is described in *Mixed-endian configuration supported* on page 6-27.

### Byte data access

The same physical byte in memory is accessed whether big-endian or little-endian:

- Unsigned byte load as described in *Load unsigned byte, endian independent* on page 6-7.
- Signed byte load as described in *Load signed byte, endian independent* on page 6-7.
- Byte store as described in *Store byte, endian independent* on page 6-8.

### Halfword data access

The same two physical bytes in memory are accessed whether big-endian or little-endian. Big-endian halfword load data is byte-reversed as read into the processor register to ensure little-endian internal representation, and similarly is byte-reversed on store to memory:

- Unsigned halfword load as described in *Load unsigned halfword, little-endian* on page 6-8 (LE), and *Load unsigned halfword, big-endian* on page 6-9 (BE-8).
- Signed halfword load as described in *Load signed halfword, little-endian* on page 6-10 (LE), and *Load signed halfword, big-endian* on page 6-10 (BE-8).
- Halfword store as described in *Store halfword, little-endian* on page 6-11 (LE), and *Store halfword, big-endian* on page 6-12 (BE-8).

**Load word**

The same four physical bytes in memory are accessed whether big-endian or little-endian. Big-endian word load data is byte reversed as read into the processor register to ensure little-endian internal representation, and similarly is byte-reversed on store to memory:

- Word load as described in *Load word, little-endian* on page 6-12 (LE), and *Load word, big-endian* on page 6-13 (BE-8).
- Word store as described in *Store word, little-endian* on page 6-14 (LE), and *Store word, big-endian* on page 6-15 (BE-8).

**Mixed-endian configuration supported**

This behavior is enabled when the U bit in CP15 Register c1 is set. This is only supported when the B bit in CP15 Register c1 is reset (Table 6-7).

**Table 6-7 Mixed-endian configuration**

| U | B | E | Instruction endianness | Data endianness     | Description                                                                          |
|---|---|---|------------------------|---------------------|--------------------------------------------------------------------------------------|
| 1 | 0 | 0 | LE                     | LE                  | LE instructions, little-endian data load/store. Unaligned data accesses are enabled. |
| 1 | 0 | 1 | LE                     | BE <sup>a</sup> -8  | LE instructions, big-endian data load/store. Unaligned data accesses are enabled.    |
| 1 | 1 | 0 | BE <sup>a</sup> -32    | BE <sup>a</sup> -32 | Word-invariant BE instructions/data. Unaligned data accesses are enabled.            |
| 1 | 1 | 1 | -                      | -                   | Reserved.                                                                            |

- a. Unaligned accesses using word-invariant BE configuration are Unpredictable. To avoid this enable strict alignment checking by setting the A bit of CP15 c1 to 1.

6.5.5     **Reset values of the U, B, and EE bits**

The reset values of the U, B, and EE bits are determined by the pins **UBITINIT**, **CFGBIGEND** set to 1, and **BIGENDINIT**, **CFGBIGEND** set to 0 (Table 6-8).

**Table 6-8 B bit, U bit, and EE bit settings**

| CFGBIGEND |            | EE | U | B |
|-----------|------------|----|---|---|
| UBITINIT  | BIGENDINIT |    |   |   |
| 0         | 0          | 0  | 0 | 0 |
| 0         | 1          | 0  | 0 | 1 |
| 1         | 0          | 0  | 1 | 0 |
| 1         | 1          | 1  | 1 | 0 |

## 6.6 Instructions to reverse bytes in a general-purpose register

When an application or device driver has to interface to memory-mapped peripheral registers or shared-memory structures that are not the same endianness as that of the internal data structures, or the endianness of the Operating System, an efficient way of being able to explicitly transform the endianness of the data is required. The following new instructions are added to the ARM and Thumb instruction sets to provide this functionality:

- reverse word (4 bytes) register, for transforming big and little-endian 32-bit representations
- reverse halfword and sign-extend, for transforming signed 16-bit representations
- reverse packed halfwords in a register for transforming big- and little-endian 16-bit representations.

These instructions are described in *About the architecture* on page 1-31.

### 6.6.1 All load and store operations

All load and store instructions take account of the CPSR E bit. Data is transferred directly to registers when E = 0, and byte reversed if E = 1 for halfword, word, or multiple word transfers. The operation is:

When CPSR[<E bit>] = 1 then byte reverse load/store data

## 6.7 Instructions to change the CPSR E bit

ARM and Thumb instructions are provided to set and clear the E bit efficiently:

SETEND BE     Sets the CPSR E bit

SETEND LE     Resets the CPSR E bit.

These are specified as unconditional operations to minimize pipelined implementation complexity.

These instructions are described in *About the architecture* on page 1-31.

# Chapter 7

## Level One Memory System

This chapter describes the ARM1156T2F-S level one memory system. It contains the following sections:

- *About the level one memory system* on page 7-2
- *Cache organization* on page 7-3
- *Tightly-coupled memory* on page 7-12
- *TCM and cache interactions* on page 7-20
- *Peripheral port* on page 7-24
- *Cache debug* on page 7-25
- *Write Buffer* on page 7-26.

## 7.1 About the level one memory system

The ARM1156T2F-S level one memory system is implementation-defined. It can consist of:

- separate instruction and data caches in a Harvard arrangement
- separate Instruction and Data *Tightly-Coupled Memory* (TCM) areas
- a Write Buffer for accesses to level two memory.

In parallel with each of the caches is an area of dedicated RAM on both the instruction and data sides. These regions are referred to as TCM. You can implement 0 or 1 TCM on each of the instruction and data sides.

Each TCM has a dedicated base address that you can place anywhere in the physical address map, and does not have to be backed by memory implemented externally. The Instruction and Data TCMs have separate base addresses.

Access to both the instruction and data sides is handled by the MPU. The MPU is responsible for protection checking, address access permissions, and memory attributes, some of which can be passed to the level two memory system.

The MPU provides the facilities required by sophisticated operating systems to deliver protected memory environments. It also supports real-time tasks with features that provide predictable execution time. For more details, see Chapter 5 *Memory Protection Unit*.

## 7.2 Cache organization

Each cache is implementation-defined and can be one, two or four-way set associative cache of configurable size. They are physically indexed and physically addressed. The cache sizes are configurable with sizes in the range of 1 to 64KB, but the maximum clock frequency might be affected if you increase the cache sizes beyond 16KB. Both the instruction cache and the data cache are capable of providing two words per cycle for all requesting sources.

The cache way size can be varied between 1KB and 16KB in powers of 2. A 1KB cache size must be implemented as a 1 way cache, and a 2KB cache must be implemented as a 2 way cache. All other cache sizes must be implemented as 4 way set associative. The cache line length is fixed at eight words (32 bytes).

The maximum cache way size that the processor supports is 16KB. The minimum cache way size that the processor supports is 1KB. You can disable instruction cache and data cache together or instruction cache and data cache individually.

### ————— Note —————

If a cache is implemented within the ARM1156T2F-S processor, way 0 must be present.

Write operations must occur after the Tag RAM reads and associated address comparisons have completed. A three-entry Write Buffer is included in the cache to enable the written words to be held until they can be written to cache. One or two words can be written in a single store operation. The addresses of these outstanding writes provide an additional input into the Tag RAM comparison for reads.

To avoid a critical path from the Tag RAM comparison to the enable signals for the data RAMs, there is a minimum of one cycle of latency between the determination of a hit to a particular way, and the start of writing to the data RAM of that way. This requires the Cache Write Buffer to be able to hold three entries, for back-to-back writes.

Accesses that read the dirty bits must also check the Cache Write Buffer for pending writes that result in dirty bits being set. The cache dirty bits for the data cache are updated when the Cache Write Buffer data is written to the RAM. This requires the dirty bits to be held as a separate storage array (significantly, the tag arrays cannot be written, because the arrays are not accessed during the data RAM writes), but permits the dirty bits to be implemented as a small RAM.

The other main operations performed by the cache are cache line refills and write-back. These occur to particular cache ways, which are determined at the point of the detection of the cache miss by the victim selection logic.

To reduce overall power consumption, the number of full cache reads is reduced by the sequential nature of many cache operations, especially on the instruction side. On a cache read that is sequential to the previous cache read, only the data RAM set that was previously read is accessed, if the read is within the same cache line. The Tag RAM is not accessed at all during this sequential operation.

Cache line refills can take several cycles. The cache line length is eight words.

The control of the level one memory system and the associated functionality, together with other system wide control attributes are handled through the system control coprocessor, CP15. This is described in Chapter 3 *System Control Coprocessor*.

Figure 7-1 on page 7-5 shows the block diagram of the cache subsystem. This figure does not show the cache refill paths.

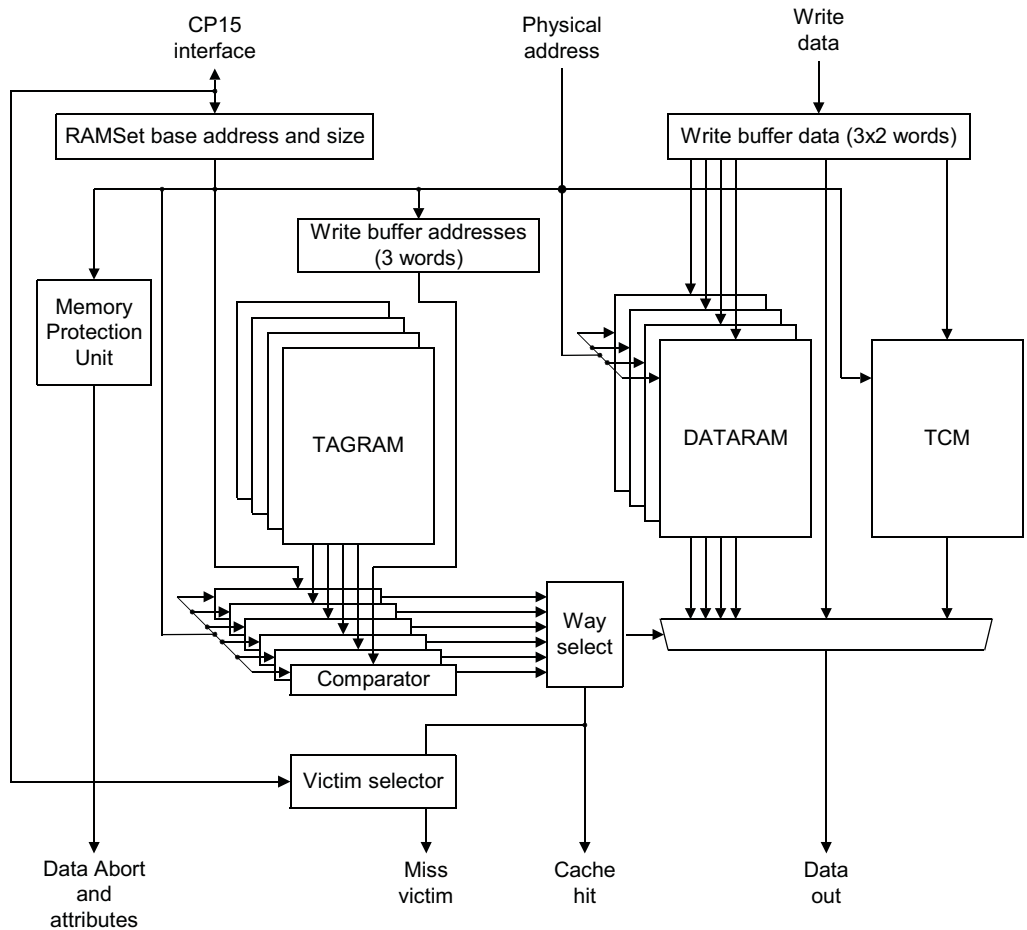

Figure 7-1 Level one cache block diagram

### 7.2.1 Features of the cache system

The level one cache system has the following features:

- The cache is a Harvard implementation.
- The caches are lockable at a granularity of a cache way, using Format C lockdown. See *c9, Data and instruction cache lockdown registers* on page 3-79.

- Cache replacement policies are Pseudo-Random or Round-Robin, as controlled by the RR bit in CP15 register c1. Round-Robin uses a single counter for all sets that selects the way used for replacement.
- Cache line allocation uses the cache replacement algorithm when all cache lines are valid. If one or more lines are invalid, then the invalid cache line with the lowest way number is allocated to in preference to replacing a valid cache line. This mechanism does not allocate to locked cache ways unless all cache ways are locked. See *Cache miss handling when all ways are locked down* on page 7-7.
- Cache lines can be either write-back or write-through, determined by the Memory Attribute.
- Only read allocation is supported.
- The cache can be disabled independently from the TCM, under control of the appropriate bits in CP15 c1.
- Data cache misses are nonblocking with a single outstanding data cache miss being supported.
- Streaming of sequential data from LDM and LDRD operations, and for sequential instruction fetches is supported.

### 7.2.2 Cache functional description

The cache and TCM exist to perform associative reads and writes on requested addresses. The steps involved in this for reads are as follows:

1. The lower bits of the address are used as the index for the tag and RAM blocks, including the TCM.
2. The physical addresses read from the Tag RAMs and the TCM base address register, and the Cache Write Buffer address registers, are compared with the physical address to form hit signals for each of the cache ways
3. The hit signals are used to select the data from the cache way that has a hit. Any bytes contained in both the data RAMs and the Cache Write Buffer entries are taken from the Cache Write Buffer. If two or three Cache Write Buffer entries are to the same bytes, the most recently written bytes are taken.

The steps for writes are as follows:

1. The lower bits of the address are used as the index for the tag blocks.

2. The physical addresses read from the Tag RAMs and the TCM base address register are compared with the physical address from the core to form hit signals for each of the cache ways.
3. If a cache way, or the TCM, has recorded a hit, then the write data is written to an entry in the Cache Write Buffer, along with the cache way, or TCM, that it must take place to.
4. The contents of the Cache Write Buffer are held until a subsequent write or CP15 operation requires space in the Write Buffer. At this point the oldest entry in the Cache Write Buffer is written into the cache.

### 7.2.3 Cache control operations

The cache control operations that are supported by the ARM1156T2F-S processor are described in *c7, Cache Operations Register* on page 3-66. ARM1156T2F-S processors support all the block cache control operations in hardware.

### 7.2.4 Cache miss handling

A cache miss results in the requests required to do the line fill being made to the level two interface, with a write-back occurring if the line to be replaced contains dirty data.

The write-back data is transferred to the Write Buffer, which is arranged to handle this data as a sequential burst. Because of the requirement for nonblocking caches, additional write transactions can occur during the transfer of write-back data from the cache to the Write Buffer. These transactions do not interfere with the burst nature of the write-back data. The Write Buffer is responsible for handling the potential *Read After Write* (RAW) data hazards that might exist from a data cache line write-back. The caches perform critical word-first cache refilling. The internal bandwidth from the level two data read port to the data caches is eight bytes per cycle, and supports streaming.

#### Cache miss handling when all ways are locked down

The ARM architecture describes the behavior of the cache as being Unpredictable when all ways in the cache are locked down. However, for the ARM1156T2F-S processor a cache miss is serviced as if Way 0 is not locked.

### 7.2.5 Cache disabled behavior

If the cache is disabled, then the cache is not accessed for reads or for writes. This ensures that maximum power savings can be achieved. It is therefore important that before the cache is disabled, all of the entries are cleaned to ensure that the external

memory has been updated. In addition, if the cache is enabled with valid entries in it, then it is possible that the entries in the cache contain old data. Therefore the cache must be disabled with clean and invalid entries.

Cache maintenance operations can be performed even if the cache is disabled.

### 7.2.6 Unexpected hit behavior

An unexpected hit is where the cache reports a hit on a memory location that is marked as Noncacheable or Shared. The unexpected hit behavior is that these hits are ignored and a level two access occurs. The unexpected hit is ignored because the cache hit signal is qualified by the cacheability.

For writes, an unexpected cache hit does not result in the cache being updated. Therefore, writes appear to be Noncacheable accesses.

If a data access lies in the range of memory specified by the Instruction TCM or Data TCM, the access is made to that RAM rather than to level two memory. This applies to both writes and reads.

### 7.2.7 Cache parity errors

The purpose of cache parity error detection is to increase the tolerance of memory faults. The inclusion of the parity generation and checking logic for the caches and the Instruction TCM is a synthesis option. For more details, see the *ARM1156T2F-S and ARM1156T2-S Implementation Guide*.

#### Instruction cache Tag and Valid RAM parity error detection

The Instruction cache Tag and Valid RAM blocks are written on cache line fills and cache maintenance operations. During the write operations the parity data is generated and written to the RAM.

The Instruction cache Tag and Valid RAM blocks are read during cache lookups and cache maintenance operations. When the IR bit is set the detection of a parity error in the Instruction cache Tag RAMs causes a cache miss indication. This invalidates the current cache line, and cause its replacement from main memory. In this case the victim counter is over-ridden and the failing set is chosen as the victim. If the IR bit, bit 6 of c1, Auxiliary Control Register, is not set the detection of a parity error causes a Prefetch Abort.

### Instruction cache Data RAM parity error detection

The instruction cache RAM block is written to on cache line fills. When the IR bit is set the detection of a parity error instruction cache RAM block causes the cache line to be invalidated and refetched from main memory. If the IR bit, bit 6 of c1, Auxiliary Control Register, is not set the detection of a parity error causes a Prefetch Abort to be returned to the processor.

When the processor executes the instruction:

- the address of the parity error is stored in the Instruction Fault Address register.
- the Instruction Fault Status register is set to indicate the presence of a parity error.

### Data cache Dirty RAM error detection

The Data cache Dirty RAM blocks are written to on line fills, stores that hit in the cache, and cache maintenance operations. If there is an error in the Dirty RAM, the cache line is treated as dirty.

### Data cache TAG and Valid RAM parity error detection

The Data Tag RAM blocks are written on cache line fills and cache maintenance operations. During the write operations the parity data is generated and written to the RAM.

The detection of a parity error in the Data cache TAG and Valid RAM blocks causes a Data Abort to be generated. The Data Fault Address Register is updated with the failing address and Fault Status Register is updated to record a parity error.

The parity fault can be precise or imprecise. See Table 7-1 on page 7-10 for more information.

### Data cache data RAM parity error detection

The data cache data RAM block is written to on cache line fills and stores that hit in the cache. The detection of a parity error in the data cache data RAM block causes a Data Abort to be returned to the processor.

The address of the data fault is stored in the Data Fault Address Register.

The Data Fault Status Register is set to indicate the presence of a parity error.

The parity fault can be precise or imprecise. See Table 7-1 on page 7-10 for more information.

## Effect of cache parity errors

Table 7-1 summarizes the effect that a particular cache parity error can have during level one memory system operations.

**Table 7-1 Effect of cache parity errors**

| Operation                          | Class of error                | Effect                                                                                                  |
|------------------------------------|-------------------------------|---------------------------------------------------------------------------------------------------------|
| Instruction fetch                  | Instruction cache Tag error   | Refresh if IR bit is enabled.                                                                           |
|                                    | Instruction cache Valid error | Prefetch Abort if IR bit is disabled.                                                                   |
|                                    | Instruction cache Data error  |                                                                                                         |
| Instruction cache maintenance (VA) | Instruction cache Tag error   | Parity errors are ignored on instruction cache maintenance operations.                                  |
|                                    | Instruction cache Valid error |                                                                                                         |
|                                    | Instruction cache Data error  |                                                                                                         |
| Data cache read (LDR/LDM)          | Data cache Tag error          | Precise Data Abort.                                                                                     |
|                                    | Data cache Valid error        |                                                                                                         |
|                                    | Data cache Data error         | Precise Data Abort in low latency or<br>Imprecise Data Abort in high performance mode.                  |
| Data cache write (STR/STM)         | Data cache Tag error          | Precise Data Abort.                                                                                     |
|                                    | Data cache Valid error        |                                                                                                         |
|                                    | Data cache Data error         | Error ignored.                                                                                          |
| Data cache eviction                | Data cache Tag error          | Imprecise abort. No AXI writes.                                                                         |
|                                    | Data cache Valid error        |                                                                                                         |
|                                    | Data cache Dirty error        |                                                                                                         |
|                                    | Data cache Data error         | Imprecise abort. AXI byte lane strobes not asserted.                                                    |
| Data cache clean (Index)           | Data cache Tag error          | Imprecise abort. No AXI write for Valid RAM error. AXI byte lane strobes not asserted for other errors. |
|                                    | Data cache Valid error        |                                                                                                         |
|                                    | Data cache Dirty error        |                                                                                                         |
|                                    | Data cache Data error         | Imprecise abort. AXI byte lane strobes not asserted.                                                    |

**Table 7-1 Effect of cache parity errors (continued)**

| Operation                  | Class of error         | Effect                                                                                                                                         |
|----------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Data cache clean (VA)      | Data cache Tag error   | Precise abort. No AXI write.                                                                                                                   |
|                            | Data cache Valid error | If an error occurs during the clean sequence:                                                                                                  |
|                            | Data cache Dirty error | <ul style="list-style-type: none"> <li>an imprecise abort is reported to the processor</li> <li>AXI byte lane strobes not asserted.</li> </ul> |
|                            |                        |                                                                                                                                                |
|                            | Data cache Data error  | Imprecise abort. AXI byte lane strobes not asserted.                                                                                           |
| Data cache Invalidate (VA) | Data cache Tag error   | Precise Abort.                                                                                                                                 |
|                            | Data cache Valid error |                                                                                                                                                |

### 7.2.8 Cache associativity

A maximum of four cache ways can be implemented in the processor. To enable smaller caches to be used with the processor, you can attach RAM to a subset of the four ways provided. Using the smallest way size, 1 KB, you can implement either:

- a direct mapped 1KB cache
- 2KB 2-way associative cache
- 4KB 4-way associative cache.

## 7.3 Tightly-coupled memory

The purpose of the *Tightly-Coupled Memory* (TCM) is to provide low-latency memory that the processor can use without the unpredictability that is a feature of caches.

You can use TCM to hold critical routines, such as interrupt handling routines or real-time tasks where the indeterminacy of a cache is highly undesirable. In addition you can use it to hold scratch pad data, data types whose locality properties are not well suited to caching, and critical data structures such as interrupt stacks.

The size of each TCM can be selected independently from a minimum of 4KB to a maximum of 256KB, in powers of 2. You can configure the TCM in several ways:

- one TCM on the instruction side and one on the data side
- one TCM on either the instruction side or the data side only
- no TCM.

The TCM Status Register in CP15 c0 identifies the TCM options and TCM sizes that have been implemented, see *c0, TCM Status Register* on page 3-24.

The Data TCM is implemented in parallel with the data cache and the Instruction TCM is implemented in parallel with the instruction cache. Each TCM has a single movable base address, specified in CP15 register c9, (see *c9, Data TCM Region Register* on page 3-82 and *c9, Instruction TCM Region Register* on page 3-83).

The size of each TCM can be different to the size of a cache way, but forms a single contiguous area of memory. The entire level one memory system is shown in Figure 7-1 on page 7-5.

You can disable each TCM to avoid an access being made to it. This gives a reduction in the power consumption. You can disable each TCM independently from the enabling of the associated cache, as determined by CP15 register c9.

Disabling the TCM invalidates the base address, so there is no unexpected hit behavior for the TCM.

The TCM region overrides memory type attributes of the MPU and all addresses within the TCM space are treated as Normal, Non-Shared memory.

### 7.3.1 TCM behavior

TCM forms a continuous area of memory that is always valid if the TCM is enabled. TCM is used as part of the physical memory map of the system, and does not have to be backed by a level of external memory with the same physical addresses. For this reason, the TCM behaves differently from the caches for regions of memory that are marked as being write-through cacheable. In such regions, no external writes occur in the event of a write to memory locations contained in the TCM.

### 7.3.2 Restriction on mappings

The TCMs are implemented in a physically indexed, physically addressed manner, giving the following behavior:

- the entries in the TCM do not have to be cleaned and/or invalidated by software
- aliases to the same physical address can exist in memory regions that are held in the TCM.

As a result, memory mapping restrictions for the TCM are less restrictive than for the cache, as described in Restrictions on accesses to different types of memory on page 6-26.

### 7.3.3 Restriction on attributes

The attributes that describe areas of memory that are handled by the TCM are ignored and access to the TCM is made, if the access permissions permit.

### 7.3.4 TCM error detection signals

Large SRAM arrays are susceptible to soft errors caused, for example, by alpha particle radiation. These errors can result in incorrect data being returned. You can use parity checking or some form of error detection and correction outside the ARM1156T2F-S processor to detect these errors. Because of the frequency at which the processor operates a pause and repair scheme is supported. This scheme enables stall cycles to be inserted if an error is detected so that the appropriate time is given to correct the memory error.

To enable the ARM1156T2F-S processor to support external error detection on the tightly-coupled memories there is one error signal for each of the TCM interfaces:

- **DTCDATAERROR[7:0]**
- **ITCDATAERROR[7:0]**

**DTCDATAERROR[7:0]** and **ITCDATAERROR[7:0]** enable the ARM1156T2F-S processor to be informed of error conditions during TCM read accesses. These signals are valid in the same clock cycle as the data returned from the TCM.

**DTCDATAERROR[7:0]** and **ITCDATAERROR[7:0]** are ignored during write accesses.

Error detection is performed externally to the ARM1156T2F-S processor. If error support is not required **DTCDATAERROR[7:0]** and **ITCDATAERROR[7:0]** must be tied LOW. For example, when using parity error detection, parity information must be generated for each byte because the ARM1156T2F-S processor is capable of performing byte accesses.

The ARM1156T2F-S processor provides parity bits for each byte written to memory using **ITCDATAPARITY[7:0]** and **DTCDATAPARITY[7:0]**. Data is always read from the TCMs in 32-bit words and a parity error in any one byte must be returned to the core as an error. The ARM1156T2F-S processor uses odd parity.

If an error is returned from the TCM interface, the relevant fault address and fault status registers are updated. For the Data TCM, an error might stall the processor for several clock cycles before the Data Abort handler is fetched.

For data reads from either Instruction TCM or Data TCM any error returned causes a Data Abort exception. The exception handler determines what corrective action, if any, to take.

For instruction fetches from the Instruction TCM any error returned causes a Prefetch Abort exception if the ARM1156T2F-S processor tries to execute the returned instruction.

———— **Note** ————

If all the data is returned from the TCM write buffer, **DTCDATAERROR[7:0]** is ignored. If only part of the data is returned from the TCM write buffer, **DTCDATAERROR[7:0]** is sampled. To prevent errors from uninitialized locations, memory must be initialized so that spurious read errors are not generated.

---

### 7.3.5 TCM accesses

This section provides examples of TCM read access, TCM write access, an error generation on read, and an error correction on read. It also provides examples on the effects of stall cycles.

#### TCM read access

Figure 7-2 on page 7-15 shows an example of a TCM read access. The processor drives the address and control to the memory on the rising edge of the processor clock. The processor clock is inverted to produce RAM clock. This signal drives the RAM block on its rising edge. This enables the processor to have a complete clock cycle for the memory access to the RAM block.

To align the data with the processor clock, a transparent latch opens at the end of the RAM access and the data is captured on the rising edge of the processor clock two cycles after the edge which started the transfer.

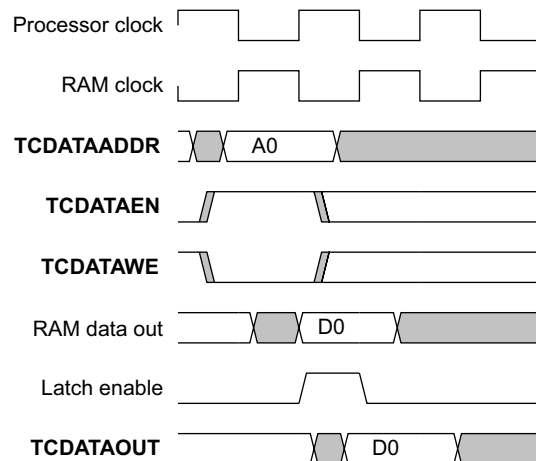

Figure 7-2 TCM read access

### TCM write access

Figure 7-3 shows an example of a TCM write access. The RAM control signals are generated from the rising edge of the processor clock, and are held for one processor clock cycle. The write data is asserted at the same time. **TCDATABW** is an eight bit bus that indicates which bytes are to be written to memory. Figure 7-32 shows that all eight bytes are written to RAM.

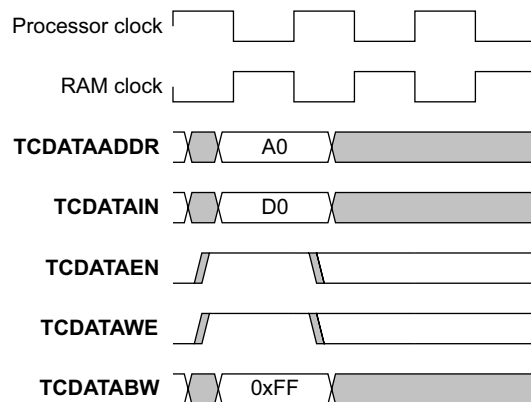

Figure 7-3 TCM write access

Error generation on read

The processor supports parity errors for the TCMs. If parity is enabled, that is bit 2 of the Auxiliary Control register is set to 1, see *c1, Auxiliary Control Register* on page 3-50, the processor generates parity bits for each byte written to the TCM. The processor implements an odd-parity scheme. The processor generates parity bits in parallel to the write data. The parity bits timing is the same as the write data.

The parity checking logic for the TCMs is added outside of the processor. For additional information see the *ARM1156T2F-S and ARM1156T2-S Integration Manual*.

Figure 7-4 shows an example of a parity error generated on a read access.

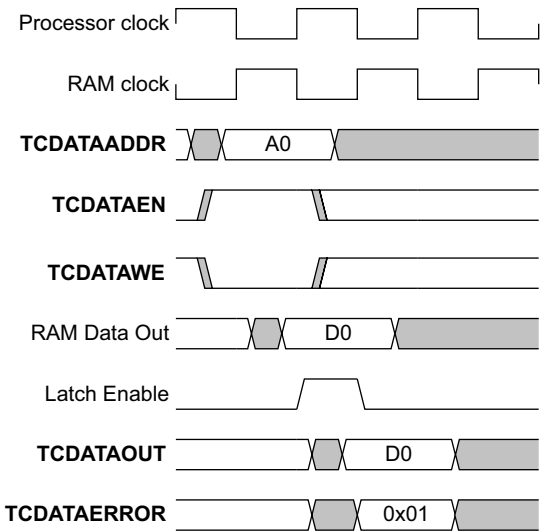

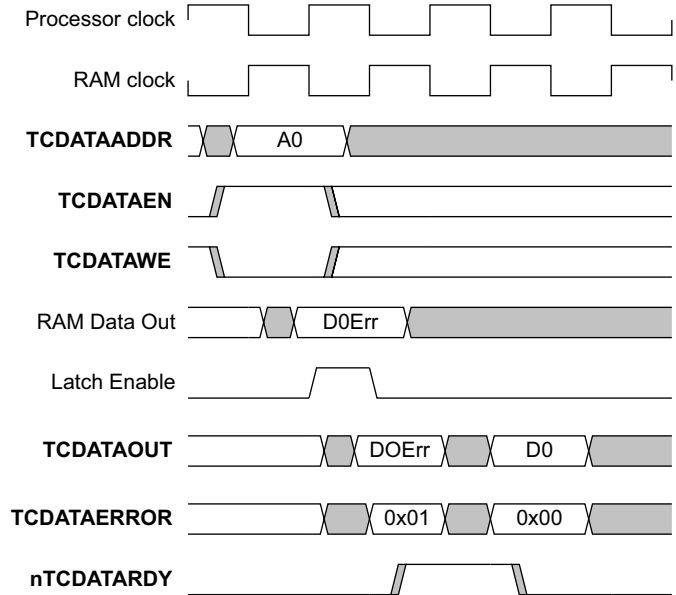

Figure 7-4 Error generation on read

Access to RAM is activated on the rising edge of the RAM clock. If parity is implemented for the TCM, the parity bits are read at the same time as the data. The parity bits are checked for each byte and a parity error is generated if the parity is incorrect. A parity error on any byte generates a data abort exception for data accesses unless the access is the result of a source misprediction. A parity error for an opcode access generates a prefetch abort exception if the access reaches the execution stage of the processor pipeline.

## Error correction on read

In systems that require fault tolerance, it is possible to implement error correction on the TCMs. Figure 7-5 shows an example where the read results in an error being detected by the external ECC logic. This error causes a stall to be inserted, **nTCDATARDY**. During this cycle, the ECC logic can attempt to correct the error using the error correction codes stored in the TCM. If this is successful, the error flags are cleared and the access completed by de-asserting **nTCDATARDY**.

**Figure 7-5 Error correction on read**

If the error correction is unsuccessful, the access completes by:

- de-asserting **nTCDATARDY**
- sending non-zero **TCDATAERROR** signals to the processor at the same time as **nTCDATARDY** is de-asserted.

## Effects of stall cycles

Because of the pipelined nature of the TCM accesses it is possible for the processor to issue three accesses before a stall is recognized. Figure 7-6 on page 7-18 shows an example of three read accesses.

Figure 7-6 Stall cycles on read accesses

The processor issues access A that causes **nTCDATARDY** to be asserted. Access B is issued before the processor can register the stall signal. Access C is issued because **nTCDATARDY** is registered by the processor before being used. This prevents the cancellation of access C.

The external wait generation logic must ignore accesses B and C. These accesses are re-issued in order by the processor.

Figure 7-7 shows that the processor can issue three write accesses before the stall signal is recognized.

Figure 7-7 Stall cycles on write accesses

The wait state generation logic must ignore the accesses when **nTCDATARDY** and a pipelined version of this signal are asserted.

Because there is a considerable delay before restarting the transactions when the processor initially registers the TCM interface outputs and the **nTCDATARDY** input, it is recommended that you do not use the stall mechanism as a wait state mechanism to support slow memories, with wait states for each access.

You can use the stall mechanism for infrequent events such as error correction or resolving arbitration clashes when an external DMA has access to the TCMs.

## 7.4 TCM and cache interactions

In the event that a TCM and a cache both contain the requested address, it is architecturally Unpredictable which memory the instruction data is returned from. It is expected that such an event only arises from a failure to invalidate the cache when the base register of the TCM is changed, and so is clearly a programming error.

For a Harvard arrangement of caches and TCM, data reads and writes can access any Instruction TCM for both reads and writes. This ensures that accesses to literal pools, Undefined instructions, and SVC numbers are possible, and aids debugging. For this reason, an Instruction TCM must behave as a unified TCM, but can be optimized for instruction fetches.

You must not program an Instruction TCM to the same base address as a Data TCM and, if the two RAM blocks are different sizes, the regions in physical memory of the two RAM blocks must not be overlapped.

In these cases, code that is intended to be ported to other ARM platforms must not rely on the behavior of ARM1156T2F-S processor.

### 7.4.1 Core access arbitration

Core accesses to both the Instruction TCM and the Data TCM can occur in parallel.

### 7.4.2 Instruction accesses to TCM

If the Instruction TCM and the instruction cache both contain the requested instruction address, the ARM1156T2F-S processor returns data from the TCM. The instruction prefetch port of the ARM1156T2F-S processor cannot access the Data TCM. If an instruction prefetch misses the Instruction TCM and instruction cache but hits the Data TCM, then the result is an access to the level two memory.

An *Instruction Memory Barrier (IMB)* must be inserted between a write to an Instruction TCM and the instructions being written being relied upon. For more details, see *Instruction Memory Barrier (IMB) instruction* on page 4-7.

### 7.4.3 Data accesses to TCMs

If the Data TCM and the data cache both contain the requested data address for a read, the ARM1156T2F-S processor returns data from the Data TCM. For a write, the write occurs to the Data TCM. The majority of data accesses go to the data cache or to the Data TCM, but occasionally a data access reads or writes the Instruction TCM. Therefore this section describes data accesses to both TCMs.

The Instruction TCM base address is read by the ARM1156T2F-S processor data port as a possible source for data for all memory accesses. This increases the address comparisons associated with the data, compared with the number required for the instruction memory lookup, for the level one memory hit generation. This functionality is required for reading literal values and for debug purposes, such as setting software breakpoints.

SWP and other memory synchronization operations, such as load-exclusive and store-exclusive, to instruction TCM are not supported, and result in Unpredictable behavior.

To save power, the processor predicts whether each data access needs to access the Data TCM. This prediction assumes that a data access will hit the Data TCM only if the previous data access hit the Data TCM. On an incorrect prediction the data access restarts, incurring a penalty of two or more cycles.

Access to the Instruction TCM involves a delay of at least three cycles in the reading or writing of the data. This delay means the Instruction TCM access can be scheduled to take place only when the presence of a hit to the Instruction TCM is known. This saves power and avoids unnecessary delays being inserted into the instruction-fetch side. This delay is applied to all accesses in a multiple operation in the case of an LDM, an LDCL, an STM, or an STCL.

The resulting behavior is architecturally Unpredictable if:

- the Instruction TCM and Data TCM have the same base address
- the regions in physical memory of the two RAMs of differing sizes are overlapped.

If an access is made to a location which is covered by both an Instruction TCM and a Data TCM, then access is to the Instruction TCM only.

It is not required for instruction port(s) to be able to access the Data TCM. An attempt to access addresses in the range covered by a Data TCM from an instruction port does not result in an access to the Data TCM. In this case, the instruction is fetched from main memory. It is anticipated that such accesses can result in external aborts in some systems, because the address range might not be supported in main memory.

Table 7-2 on page 7-22 summarizes the results of data accesses to TCM and the cache. This also embodies the unexpected hit behavior for the cache described in *Unexpected hit behavior* on page 7-8.

The hit to the Data TCM and Instruction TCM refers to hitting an address in the range covered by that TCM.

**Table 7-2 Summary of data accesses to TCM and caches**

| <b>Data TCM</b> | <b>Data cache<sup>a</sup></b> | <b>Instruction TCM</b> | <b>Read behavior</b>                                                                                                   | <b>Write behavior</b>                                                                                                               |

a. excludes unexpected hit

Table 7-3 summarizes the results of instruction accesses to TCM and the cache. This also embodies the unexpected hit behavior for the cache described in *Unexpected hit behavior* on page 7-8. In Table 7-3, the instruction cache can only be hit if the memory location being accessed is marked as being Cacheable and not shareable. The hit to the Instruction TCM refers to hitting an address in the range covered by that TCM.

**Table 7-3 Summary of instruction accesses to TCM and caches**

| Instruction TCM | Instruction cache | Data TCM   | Read behavior                                                                                            |
|-----------------|-------------------|------------|----------------------------------------------------------------------------------------------------------|
| Hit             | Hit               | Don't care | Read from Instruction TCM. No linefill to instruction cache even if marked Cacheable.                    |
|                 | Miss              | Don't care |                                                                                                          |
| Miss            | Hit               | Don't care | Read from instruction cache.                                                                             |
| Miss            | Miss              | Don't care | If Cacheable and cache enabled, cache linefill.<br>If Noncacheable or cache disabled, read to level two. |

## 7.5 Peripheral port

The peripheral port is accessed by memory locations whose attributes are Non-Shared Device. When the MPU is disabled a default memory region is used to access the peripheral port. This mapping only occurs while the MPU is disabled.

Peripheral port data accesses are to the Device and Non-Shared memory region.

If the region of memory mapped by this mechanism overlaps with the regions of memory that are contained within the TCMs, then the memory locations that are mapped as both TCM and Non-Shared Device are treated as TCM. Therefore, the overlapping region does not access the peripheral port.

## 7.6 Cache debug

The debug architecture for the ARM1156T2F-S processor is described in Chapter 13 *Debug*. The External Debug Interface is based on JTAG, and is described in Chapter 14 *Debug Test Access Port*. The debug architecture enables the cache debug to be defined by the implementation. This functionality is defined here. The debugger examines the contents of the instruction and data caches during debug operations. This is achieved in two stages:

1. Reading the Tag RAM entries for each cache location.
2. Reading the data values for those addresses.

The debugger determines which valid addresses are stored in the cache. This is done by reading the instruction and data cache Tag arrays using a CP15 instruction executed using the Instruction Transfer Register. The *Instruction Transfer Register* (ITR) is accessed using scan chain 4 as described in *Scan chain 4, Instruction Transfer Register (ITR)* on page 14-14. The debugger must do this for each entry of each set within the cache. This access is performed by an MCR that transfers from the ARM register the Set and Index of the required line in the Tag RAM array. The contents of the line are then returned to the Instruction or Data Debug Cache Register as appropriate.

## 7.7 Write Buffer

All memory writes take place using the Write Buffer. To ensure that the Write Buffer is not drained on reads, the following features are implemented:

- The Write Buffer is a FIFO of outstanding writes to memory. It consists of a set of addresses and a set of data words (together with their size information).
- If a sequence of data words is contained in the Write Buffer, these are denoted as applying to the same address by the Write Buffer storing the size of the store multiple. This reduces the number of address entries that have to be stored in the Write Buffer.
- In addition to this, a separate FIFO of write-back addresses and data words is implemented. Having a separate structure avoids complications associated with performing an external write while the write-through is being handled.
- The address of a new read access is compared against the addresses in the Write Buffer. If a read is to a location that is already in the Write Buffer, the read is blocked until the Write Buffer has drained sufficiently far for that location to be no longer in the Write Buffer. The sequential marker only applies to words in the same 8 word (8 word aligned) block, and the address comparisons are based on 8 word aligned addresses.

The ordering of memory accesses is described in *Ordering requirements for memory accesses* on page 5-14.

# Chapter 8

## Level Two Interface

The processor is designed to be used within larger chip designs using the *Advanced Microcontroller Bus Architecture* (AMBA) AXI protocol. The processor uses the level two interface as its interface to memory and peripherals. This chapter describes the features of the level two interface not covered in the *AMBA AXI Protocol Specification*

The chapter contains the following sections:

- *About the level two interface* on page 8-2
- *Synchronization primitives* on page 8-6
- *AXI control signals in the processor* on page 8-8
- *Instruction fetch interface transfers* on page 8-16
- *Data read/write interface transfers* on page 8-18
- *Peripheral interface transfers* on page 8-45
- *Endianness* on page 8-47
- *Locked access* on page 8-49.

## 8.1 About the level two interface

The level two memory interface exists to provide a high-bandwidth interface to second level caches, on-chip RAM, peripherals, and interfaces to external memory.

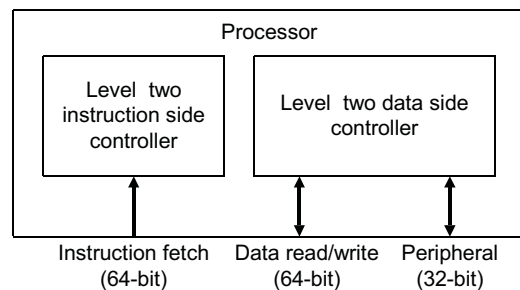

It is a key feature in ensuring high system performance, providing a higher bandwidth mechanism for filling the caches in a cache miss than has existed on previous ARM processors.

The processor level two interconnect system uses the following 64-bit wide AXI interfaces:

- Instruction fetch interface
- Data read/write interface.

Another interface is also provided. The Peripheral interface is a 32-bit AXI interface.

Figure 8-1 shows the level two interconnect interfaces.

**Figure 8-1 Level two interconnect interfaces**

These interfaces provide for several simultaneous outstanding transactions, giving the potential for high performance from level two memory systems that support parallelism, and also for high utilization of pipelined memories such as SDRAM.

- The data read/write port can issue outstanding accesses. The maximum number of outstanding accesses it can issue is two reads and two writes, to give a total of four outstanding accesses.
- The instruction port can issue outstanding read accesses, up to a maximum of two outstanding read accesses.
- No outstanding accesses are issued by the peripheral port.

Each of the three wide interfaces is an AXI interface, with additional signals to support additional features for the level two memory system for multi-level cache support.

The processor does not drive the following ID signals:

- **ARIDI**
- **ARIDRW**
- **AWIDRW**
- **WIDRW**
- **ARIDP**
- **AWIDP**
- **WIDP**
- **ARIDD**
- **AWIDD**
- **WIDD.**

When you connect the processor in an AXI system, you can choose whatever value suits your system. The only requirement is that **AWID** and **WID** must have the same value.

Table 8-1 shows the AXI parameters for the level 2 interconnect interfaces.

**Table 8-1 AXI parameters for the level 2 interconnect interfaces**

| Parameter                   | Interface                   |                             |                             |
|-----------------------------|-----------------------------|-----------------------------|-----------------------------|
|                             | Instruction, RO             | Data, RW                    | Peripheral, RW              |
| Write Issuing Capability    | Not applicable              | 2                           | 1                           |
| Read Issuing Capability     | 2                           | 2                           | 1                           |
| Combined Issuing Capability | Not applicable              | 4                           | 1                           |
| Write ID Capability         | Not applicable              | 1                           | 1                           |
| Write Interleave Capability | Not applicable              | 1 <sup>a</sup>              | 1 <sup>a</sup>              |
| Write ID Width              | Not applicable <sup>b</sup> | Not applicable <sup>b</sup> | Not applicable <sup>b</sup> |
| Read ID Capability          | 1                           | 1                           | 1                           |
| Read ID Width               | Not applicable <sup>b</sup> | Not applicable <sup>b</sup> | Not applicable <sup>b</sup> |

a. The value of 1 means that interleaving or re-ordering cannot occur.

b. The level 2 interconnect interfaces do not implement any AXI ID signals

### 8.1.1 Level two instruction-side controller

The level two instruction-side controller contains the level two Instruction fetch interface. See *Instruction fetch interface*.

The level two instruction-side controller handles all instruction-side cache misses including those for Noncacheable locations. It is responsible for the sequencing of cache operations for instruction cache linefills, making requests for the individual stores through the *Prefetch Unit* (PFU) to the instruction cache. The decoupling involved means that the level two instruction-side controller contains some buffering.

#### Instruction fetch interface

The Instruction fetch interface is a read-only interface that services the instruction cache on cache misses, including the fetching of instructions for the PU that are held in memory marked as Noncacheable. The interface is optimized for cache linefills rather than individual requests.

### 8.1.2 Level two data-side controller

The level two data-side controller is responsible for the level two:

- Data read/write interface
- Peripheral interface.

The level two data-side controller handles:

- All external access requests from the Load Store Unit, including cache misses, data Write-Through operations, and Noncacheable data.
- SWP instructions and semaphore operations. It schedules all reads and writes on the two interfaces, that are closely related.

The level two data-side controller also handles the Peripheral interface.

The level two data-side controller contains the Refill and Write-Back engines for the data cache. These make requests through the Load Store Unit for the individual cache operations that are required. The decoupling involved means that the level two data-side controller contains some buffering. The write buffer is an integral part of the level two data-side controller.

## Data read/write interface

The Data read/write interface performs reads and swap reads. It services the data cache on cache misses, and reads Noncacheable locations.

The Data read/write interface performs writes and swap writes. It services the writes out of the Write Buffer. Multiple writes can be queued up as part of this interface.

## Peripheral interface

The Peripheral interface is an AXI interface that services peripheral devices. The Peripheral interface is used for peripherals that are private to the processor, such as the Vectored Interrupt Controller or Watchdog Timer. Accesses to regions of memory that are marked as Device and Non-Shared are routed to the Peripheral interface in preference to the Data read/write interface.

Unaligned accesses and exclusive accesses are not supported by the peripheral port because they are not supported in Device memory. The order in which accesses are presented on the Peripheral interface, relative to those on the Data read/write interface is not defined, other than Strongly Ordered accesses. For this reason, the peripheral port is expected to be used to access a bus or memory system which is not accessible through the data read and data write ports. See Chapter 5 *Memory Protection Unit* and *Peripheral port* on page 7-24 to find out how to remap data accesses to a defined address region to the peripheral port

## 8.2 Synchronization primitives

On previous architectures support for shared memory synchronization has been with the read-locked-write operations that swap register contents with memory, the SWP and SWPB instructions. These support basic busy and free semaphore mechanisms. For details of the swap instructions, and how to use them to implement semaphores, see the *ARM Architecture Reference Manual*.

ARMv6 and its extensions introduce support for more comprehensive shared-memory synchronization primitives that scale for multiple-processor system designs. Two instructions are introduced that support multiple-processor and shared-memory inter-process communication:

- load-exclusive, LDREX
- store-exclusive, STREX.

The exclusive-access instructions rely on the ability to tag a physical address as exclusive-access for a particular processor. This tag is later used to determine if an exclusive store to an address occurs. For non-shared memory regions, the LDREX and STREX instructions are presented to the ports as normal LDR or STR. If a processor does an STR on a memory region that it has already marked as exclusive, this does not clear the tag. However, if the region has been marked by another processor, an STR clears the tag. Other events might cause the tag to be cleared. In particular, for memory regions that are not shared, it is Unpredictable whether a store by another processor to a tagged physical address causes the tag to be cleared. An external abort on either a load-exclusive or store-exclusive puts the processor into Abort mode.

### ————— Note —————

The processor has an internal monitor that keeps track of the state of the regions marked as Non-Shared. An external abort on a load-exclusive can leave internal monitor in its exclusive state and might affect your software. If it does you must ensure that a store-exclusive to an unused location is executed in your abort handler to clear the processor internal monitor to an open state.

### 8.2.1 Load-exclusive instruction

Load-exclusive performs a load from memory and causes the physical address of the access to be tagged as exclusive-access for the requesting processor. This causes any other physical address that has been tagged by the requesting processor to no longer be tagged as exclusive-access.

### 8.2.2 Store-exclusive instruction

Store-exclusive performs a conditional store to memory. The store only takes place if the physical address is tagged as exclusive-access for the requesting processor. This operation returns a status value. If the store updates memory the return value is 0, otherwise it is 1. In both cases, the physical address is no longer tagged as exclusive-access for any processor.

### 8.2.3 Example of LDREX and STREX usage

This is an example of typical usage. Suppose you are trying to claim a lock:

```

Lock address LockAddr
Lock free 0x00
Lock taken 0xFF
try MOV R1, #0xFF ; load the 'lock taken' value
 LDREX R0, [LockAddr] ; load the lock value
 CMP R0, #0 ; is the lock free?
 STREXEQ R0, R1, [LockAddr] ; try and claim the lock
 CMPEQ R0, #0 ; did this succeed?
 BNE try ; no - try again
 ; yes - we have the lock

```

The typical case, where the lock is free and you have exclusive-access, is six instructions.

### 8.3 AXI control signals in the processor

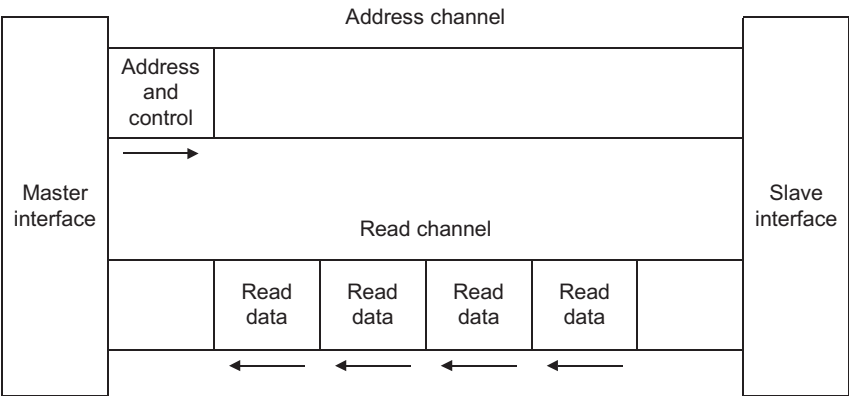

This section describes the processor implementation of the AXI control signals:

For additional information about AXI, see the *AMBA AXI Protocol Specification*.

The AXI protocol is burst-based. Every transaction has address and control information on the address channel that describes the nature of the data to be transferred. The data is transferred between master and slave using a write channel to the slave or a read channel to the master. In write transactions, where all the data flows from the master to the slave, the AXI has an additional write response channel to enable the slave to signal to the master the completion of the write transaction.

The AXI protocol permits address information to be issued ahead of the actual data transfer and enables support for multiple outstanding transactions in addition to out-of-order completion of transactions.

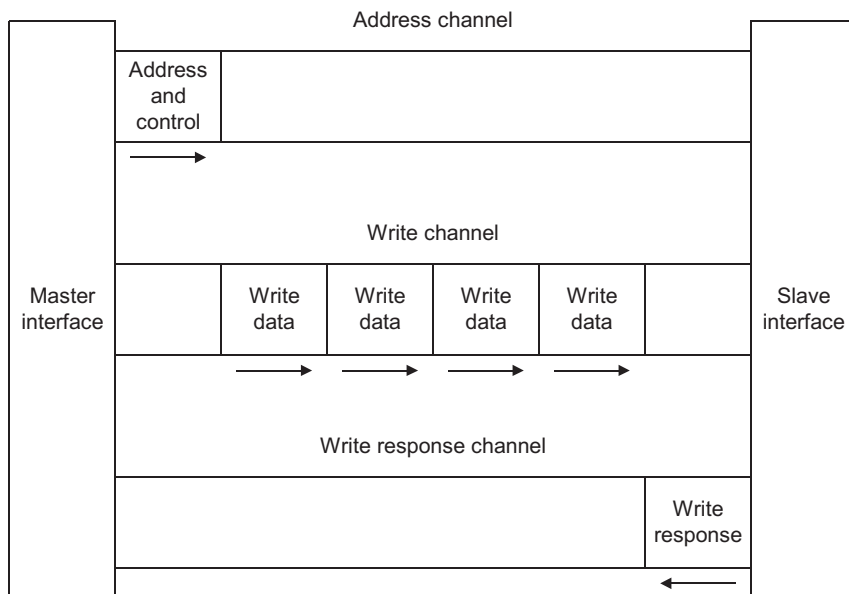

Figure 8-2 shows how a read transaction uses the read address and read data channels.

**Figure 8-2 Channel architecture of reads**

Figure 8-3 on page 8-9 shows how a write transaction uses the write address, write data, and write response channels.

**Figure 8-3 Channel architecture of writes**

### 8.3.1 Channel definition

Each of the five independent channels consists of a set of information signals and uses a two-way **VALID** and **READY** handshake mechanism.

The information source uses the **VALID** signal to show when valid data is available on the channel. The destination uses the **READY** signal to show when it can accept the data. Both the read data channel and the write data channel also include a **LAST** signal to indicate when the transfer of the final data item within a transaction takes place.

#### Read Address channel

The read address channel is used in every transaction and carries all the required read address and control information for that transaction. The AXI supports the following mechanisms:

- variable-length bursts, from 1 to 16 data transfers per burst
- bursts with a transfer size of eight bits up to the maximum data bus width
- wrapping, incrementing, and fixed address bursts
- atomic operations, using exclusive and locked access

- system-level caching and buffering control
- Secure and privileged access.

### **Write address channel**

The write address channel is used in every transaction and carries all the required write address and control information for that transaction. The AXI supports the following mechanisms:

- variable-length bursts, from 1 to 16 data transfers per burst
- bursts with a transfer size of eight bits up to the maximum data bus width
- wrapping, incrementing, and fixed address bursts
- atomic operations, using exclusive and locked access
- system-level caching and buffering control
- Secure and privileged access.

### **Read data channel**

The read data channel conveys both the read data and any read response information from the slave back to the master. The read data channel includes:

- the data bus, that is 32 bits wide for the Peripheral port, and 64 bits wide for the Data read/write port and Instruction port
- a read response indicating the completion status of the read transaction.

### **Write data channel**

The write data channel conveys the write data from the master to the slave and includes:

- the data bus, that is 32 bits wide for the Peripheral port, and 64 bits wide for the Data read/write port and Instruction port
- one byte lane strobe for every eight data bits, indicating the bytes of the data bus that are valid.

### **Write response channel**

The write response channel provides a way for the slave to respond to write transactions. All write transactions use completion signaling.

---

#### **Note**

The completion signal occurs once for each burst, not for each individual data transfer within the burst.

---

8.3.2 Signal name suffixes

The signal name for each of the interfaces denotes the interface that it applies to. The signals have one of these suffixes:

- I** Instruction fetch interface.
- RW** Data read/write interface.
- P** Peripheral interface.

The second character in the signal name indicates if the data direction is a read, **R**, or write, **W**.

For example, **AxSIZE[2:0]** is called **ARSIZEI[2:0]** for reads in the Instruction fetch interface.

8.3.3 Address channel signals

The address channel control signals in the processor are:

- AxLEN[3:0]*
- AxSIZE[2:0]* on page 8-12
- AxBURST[1:0]* on page 8-12
- AxLOCK[1:0]* on page 8-13
- AxCACHE[3:0]* on page 8-13
- AxPROT[2:0]* on page 8-13
- AxSIDE BAND[4:0]* on page 8-14.

**AxLEN[3:0]**

The **AxLEN[3:0]** signal indicates the number of transfers in a burst. Table 8-2 lists the values of **AxLEN** that the processor uses.

Table 8-2 AxLEN[3:0] encoding

| AxLEN[3:0] | Number of data transfers |
|------------|--------------------------|
| b0000      | 1                        |
| b0001      | 2                        |
| b0010      | 3                        |
| b0011      | 4                        |
| b0100      | 5                        |

Table 8-2 AxLEN[3:0] encoding (continued)

| AxLEN[3:0] | Number of data transfers |
|------------|--------------------------|
| b0101      | 6                        |
| b0110      | 7                        |
| b0111      | 8                        |

AxSIZE[2:0]

This signal indicates the size of each transfer. Table 8-3 lists the supported transfer sizes.

Table 8-3 AxSIZE[2:0] encoding

| AxSIZE[2:0] | Bytes in transfer |
|-------------|-------------------|
| b000        | 1                 |
| b001        | 2                 |
| b010        | 4                 |
| b011        | 8                 |

AxBURST[1:0]

The **AxBURST[1:0]** signals indicate a fixed, incrementing or wrapping burst. Table 8-4 lists the burst types that the ARM1156T2F-S processor supports.

Table 8-4 AxBURST[1:0] encoding

| AxBURST[2:0] | Burst type | Description                                                                   |
|--------------|------------|-------------------------------------------------------------------------------|
| b00          | Fixed      | Fixed address burst                                                           |
| b01          | Incr       | Incrementing address burst                                                    |
| b10          | Wrap       | Incrementing address burst that wraps to a lower address at the wrap boundary |

The processor uses:

- Wrapping bursts for some cache line fills
- Incrementing bursts for accesses to Noncacheable memory, including instruction fetches.

**AxLOCK[1:0]**

The **AxLOCK[1:0]** signal indicates the lock type of access. The processor supports all locked type accesses. The instruction port only generates Normal access types. The Data read/write port generates all access types, Normal, exclusive and locked access.

Table 8-5 lists the values of **AxLOCK** that the processor supports.

**Table 8-5 AxLOCK[1:0] encoding**

| AxLOCK[1:0] | Description      |
|-------------|------------------|
| b00         | Normal access    |
| b01         | Exclusive access |
| b10         | Locked access    |

**AxCACHE[3:0]**

The **AxCACHE[3:0]** signals indicate the bufferable, cacheable, write-through, write-back, and allocate attributes of the transaction. These attributes are for the level two memory system. Table 8-6 lists the correspondence between the **AxCACHE[3:0]** encoding and cacheable attributes.

**Table 8-6 AxCACHE[3:0] encoding**

| AxCACHE[3:0] | Transaction attributes                    |
|--------------|-------------------------------------------|
| b0000        | Strongly ordered                          |
| b0001        | Shared device or non-shared device        |
| b0010        | Outer Noncacheable                        |
| b0110        | Outer write-through, no allocate on write |
| b0111        | Outer write-back, no allocate on write    |
| b1111        | Outer write-back, write allocate.         |

**AxPROT[2:0]**

The **AxPROT[2:0]** signal marks the protection level of the transaction, that is if the transaction is user or privileged, or secure. The signal also indicates if the transaction is a data access or an instruction access.

All transactions from the instruction port are marked as instruction accesses (**ARPROTI**[2] = 1). Transactions on the peripheral and data read/write ports are marked as data accesses.

Table 8-7 lists the supported values for **AxPROT**[2:0].

Table 8-7 **AxPROT**[2:0] encoding

| Signal            | Description                               |
|-------------------|-------------------------------------------|
| <b>AxPROT</b> [2] | 0 = Data access<br>1 = Instruction access |
| <b>AxPROT</b> [1] | 0 = Always secure                         |
| <b>AxPROT</b> [0] | 0 = User<br>1 = Privileged                |

**AxSIDEBAND**[4:0]

The **AxSIDEBAND**[4:1] signals indicate the bufferable, cacheable, write-through, write-back, and allocate attributes of the level one memory. **AxSIDEBAND**[0] indicates the Shared attribute. Table 8-8 lists the correspondence between the **AxSIDEBAND**[4:1] encoding and the cacheable attributes for the read/write and Peripheral ports.

Table 8-8 **AxSIDEBAND**[4:1] encoding

| <b>AxSIDEBAND</b> [4:1] | Transaction attributes                        |
|-------------------------|-----------------------------------------------|
| b0000                   | Strongly ordered                              |
| b0001                   | Shared device or non-shared device            |
| b0010                   | Inner Noncacheable                            |
| b0110                   | Inner write-through, no allocate on write     |
| b0111                   | Inner write-back, no allocate on write        |
| b1111                   | Inner write-back, write allocate <sup>a</sup> |

a. The ARM1156T2F-S processor does not support write allocate.

Table 8-9 lists the correspondence between the **ARSIDEBANDI[4:1]** encoding and the cacheable attributes for the Instruction port.

**Table 8-9 ARSIDEBANDI[4:1] encoding**

| <b>ARSIDEBANDI[4:1]</b> | <b>Transaction attributes</b> |
|-------------------------|-------------------------------|
| b0000                   | Strongly Ordered              |
| b0001                   | Device                        |
| b0010                   | Inner Noncacheable            |
| b0110                   | Inner Cacheable               |

These signals are not part of the AXI protocol and are added for additional information.

## 8.4 Instruction fetch interface transfers

The tables in this section describe the AXI interface behavior for instruction side fetches to either Cacheable or Noncacheable regions of memory for the following interface signals:

- **ARBURSTI**[1:0]
- **ARLENI**[3:0]
- **ARADDRI**[31:0]
- **ARSIZEI**[2:0].

See the *AMBA AXI Protocol Specification* for details of the other AXI signals.

### 8.4.1 Cacheable fetches

Table 8-10 lists the values of **ARADDRI**, **ARBURSTI**, **ARSIZEI**, and **ARLENI** for Cacheable fetches.

Table 8-10 AXI signals for Cacheable fetches

| Address[4:0] | ARADDRI | ARBURSTI | ARSIZEI | ARLENI           |
|--------------|---------|----------|---------|------------------|
| 0x00, word 0 | 0x00    | Incr     | 64-bit  | 4 data transfers |
| 0x04, word 1 | 0x00    | Incr     | 64-bit  | 4 data transfers |
| 0x08, word 2 | 0x08    | Wrap     | 64-bit  | 4 data transfers |
| 0x0C, word 3 | 0x08    | Wrap     | 64-bit  | 4 data transfers |
| 0x10, word 4 | 0x10    | Wrap     | 64-bit  | 4 data transfers |
| 0x14, word 5 | 0x10    | Wrap     | 64-bit  | 4 data transfers |
| 0x18, word 6 | 0x18    | Wrap     | 64-bit  | 4 data transfers |
| 0x1C, word 7 | 0x18    | Wrap     | 64-bit  | 4 data transfers |

8.4.2 Noncacheable fetches

Table 8-11 lists the values of **ARADDRI**, **ARBURSTI**, **ARSIZEI**, and **ARLENI** for Noncacheable fetches.

Table 8-11 AXI signals for Noncacheable fetches

| Address[4:0] | ARADDRI | ARBURSTI | ARSIZEI | ARLENI           |
|--------------|---------|----------|---------|------------------|
| 0x00, word 0 | 0x00    | Incr     | 64-bit  | 4 data transfers |
| 0x04, word 1 | 0x04    | Incr     | 64-bit  | 4 data transfers |
| 0x08, word 2 | 0x08    | Incr     | 64-bit  | 3 data transfers |
| 0x0C, word 3 | 0x0C    | Incr     | 64-bit  | 3 data transfers |
| 0x10, word 4 | 0x10    | Incr     | 64-bit  | 2 data transfers |
| 0x14, word 5 | 0x14    | Incr     | 64-bit  | 2 data transfers |
| 0x18, word 6 | 0x18    | Incr     | 64-bit  | 1 data transfer  |
| 0x1C, word 7 | 0x1C    | Incr     | 64-bit  | 1 data transfer  |

## 8.5 Data read/write interface transfers

The tables in this section describe the AXI interface behavior for Data read/write interface transfers for the following interface signals:

- **AxBURSTRW[1:0]**
- **AxLENRW[3:0]**
- **AxSIZERW[2:0]**
- **AxADDRRW[31:0]**
- **WSTRBRW[7:0]**.

### 8.5.1 Linefills

A linefill comprises four accesses to the data cache if there is no external abort returned. In the event of an external abort, the doubleword and subsequent doublewords are not written into the data cache and the line is never marked as Valid. The four accesses are:

- Write Tag and data doubleword
- Write data doubleword
- Write data doubleword
- Write Valid = 1, Dirty = 0, and data doubleword.

The linefill can only progress to attempt to write a doubleword if it does not contain dirty data. This is determined in one of two ways:

- if the victim cache line is not valid, then there is no danger and the linefill progresses
- if the victim line is valid, a signal encodes the doublewords that are clean, either because they were not dirty or they have been cleaned.

The order of words written into the cache is critical-word first, wrapping at the upper cache line boundary.

Table 8-12 on page 8-19 lists the values of **ARADDRRW**, **ARBURSTRW**, **ARSIZERW**, and **ARLENRW** for linefills.

Table 8-12 Linefill behavior on the AXI interface

| Address[4:0] | ARADDRW | ARBURSTRW | ARSIZERW | ARLENRW          |
|--------------|---------|-----------|----------|------------------|
| 0x00-0x07    | 0x00    | Incr      | 64-bit   | 4 data transfers |
| 0x08-0x0F    | 0x08    | Wrap      | 64-bit   | 4 data transfers |
| 0x10-0x17    | 0x10    | Wrap      | 64-bit   | 4 data transfers |
| 0x18-0x1F    | 0x18    | Wrap      | 64-bit   | 4 data transfers |

### 8.5.2 Noncacheable LDRB

Table 8-13 lists the values of **ARADDRW**, **ARBURSTRW**, **ARSIZERW**, and **ARLENRW** for Noncacheable LDRBs from bytes 0-7.

Table 8-13 Noncacheable LDRB

| Address[4:0] | ARADDRW | ARBURSTRW | ARSIZERW | ARLENRW         |
|--------------|---------|-----------|----------|-----------------|
| 0x00, byte 0 | 0x00    | Incr      | 8-bit    | 1 data transfer |
| 0x01, byte 1 | 0x01    | Incr      | 8-bit    | 1 data transfer |
| 0x02, byte 2 | 0x02    | Incr      | 8-bit    | 1 data transfer |
| 0x03, byte 3 | 0x03    | Incr      | 8-bit    | 1 data transfer |
| 0x04, byte 4 | 0x04    | Incr      | 8-bit    | 1 data transfer |
| 0x05, byte 5 | 0x05    | Incr      | 8-bit    | 1 data transfer |
| 0x06, byte 6 | 0x06    | Incr      | 8-bit    | 1 data transfer |
| 0x07, byte 7 | 0x07    | Incr      | 8-bit    | 1 data transfer |

8.5.3 Noncacheable LDRH

Table 8-14 lists the values of **ARADDRRW**, **ARBURSTRW**, **ARSIZERW**, and **ARLENRW** for Noncacheable LDRHs from bytes 0-7.

Table 8-14 Noncacheable LDRH

| Address[4:0] | ARADDRRW | ARBURSTRW | ARSIZERW | ARLENRW         |
|--------------|----------|-----------|----------|-----------------|
| 0x00, byte 0 | 0x00     | Incr      | 16-bit   | 1 data transfer |
| 0x01, byte 1 | 0x01     | Incr      | 32-bit   | 1 data transfer |
| 0x02, byte 2 | 0x02     | Incr      | 16-bit   | 1 data transfer |
| 0x03, byte 3 | 0x03     | Incr      | 8-bit    | 1 data transfer |
|              | 0x04     | Incr      | 8-bit    | 1 data transfer |
| 0x04, byte 4 | 0x04     | Incr      | 16-bit   | 1 data transfer |
| 0x05, byte 5 | 0x05     | Incr      | 32-bit   | 1 data transfer |
| 0x06, byte 6 | 0x06     | Incr      | 16-bit   | 1 data transfer |
| 0x07, byte 7 | 0x07     | Incr      | 8-bit    | 1 data transfer |
|              | 0x08     | Incr      | 8-bit    | 1 data transfer |

8.5.4 Noncacheable LDR or LDM1

Table 8-15 lists the values of **ARADDRRW**, **ARBURSTRW**, **ARSIZERW**, and **ARLENRW** for Noncacheable LDR or LDM1s.

Table 8-15 Noncacheable LDR or LDM1

| Address[4:0]         | ARADDRRW | ARBURSTRW | ARSIZERW | ARLENRW         |
|----------------------|----------|-----------|----------|-----------------|
| 0x00, byte 0, word 0 | 0x00     | Incr      | 32-bit   | 1 data transfer |
| 0x01, byte 1         | 0x01     | Incr      | 32-bit   | 1 data transfer |
|                      | 0x04     | Incr      | 8-bit    | 1 data transfer |
| 0x02, byte 2         | 0x02     | Incr      | 16-bit   | 1 data transfer |
|                      | 0x04     | Incr      | 16-bit   | 1 data transfer |

**Table 8-15 Noncacheable LDR or LDM1 (continued)**

| <b>Address[4:0]</b>  | <b>ARADDRRW</b> | <b>ARBURSTRW</b> | <b>ARSIZERW</b> | <b>ARLENRW</b>  |
|----------------------|-----------------|------------------|-----------------|-----------------|
| 0x03, byte 3         | 0x03            | Incr             | 8-bit           | 1 data transfer |
|                      | 0x04            | Incr             | 32-bit          | 1 data transfer |
| 0x04, byte 4, word 1 | 0x04            | Incr             | 32-bit          | 1 data transfer |
| 0x05, byte 5         | 0x05            | Incr             | 32-bit          | 1 data transfer |
|                      | 0x08            | Incr             | 8-bit           | 1 data transfer |
| 0x06, byte 6         | 0x06            | Incr             | 16-bit          | 1 data transfer |
|                      | 0x08            | Incr             | 16-bit          | 1 data transfer |
| 0x07, byte 7         | 0x07            | Incr             | 8-bit           | 1 data transfer |
|                      | 0x08            | Incr             | 32-bit          | 1 data transfer |

### 8.5.5 Noncacheable LDRD or LDM2

Table 8-16 lists the values of **ARADDRRW**, **ARBURSTRW**, **ARSIZERW**, and **ARLENRW** for Noncacheable LDRDs or LDM2s addressing words 0 to 6.

A Noncacheable LDRD or LDM2 addressing word 7 is split into two LDRs, as shown in Table 8-17 on page 8-22.

**Table 8-16 Noncacheable LDRD or LDM2**

| <b>Address[4:0]</b> | <b>ARADDRRW</b> | <b>ARBURSTRW</b> | <b>ARSIZERW</b> | <b>ARLENRW</b>   |
|---------------------|-----------------|------------------|-----------------|------------------|
| 0x00, word 0        | 0x00            | Incr             | 64-bit          | 1 data transfer  |
| 0x04, word 1        | 0x04            | Incr             | 32-bit          | 2 data transfers |
| 0x08, word 2        | 0x08            | Incr             | 64-bit          | 1 data transfer  |
| 0x0C, word 3        | 0x0C            | Incr             | 32-bit          | 2 data transfers |
| 0x10, word 4        | 0x10            | Incr             | 64-bit          | 1 data transfer  |
| 0x14, word 5        | 0x14            | Incr             | 32-bit          | 2 data transfers |
| 0x18, word 6        | 0x18            | Incr             | 64-bit          | 1 data transfer  |

Table 8-17 Noncacheable LDRD or LDM2 from word 7

| Address[4:0] | Operations                    |
|--------------|-------------------------------|
| 0x1C, word 7 | LDR from 0x1C + LDR from 0x00 |

8.5.6 Noncacheable LDM3

The values of **ARADDRRW**, **ARBURSTRW**, **ARSizerw**, and **ARLENrw** for Noncacheable LDM3s addressing words 0 to 5 are shown in:

- Table 8-18 for a load from Strongly Ordered or Device memory
- Table 8-19 for a load from Noncacheable memory or when the cache is disabled.

A Noncacheable LDM3 addressing word 6 or 7 is split into two operations as shown in Table 8-20 on page 8-23.

Table 8-18 Noncacheable LDM3, Strongly Ordered or Device memory

| Address[4:0] | ARADDRRW | ARBURSTRW | ARSIZERW | ARLENRW          |
|--------------|----------|-----------|----------|------------------|
| 0x00, word 0 | 0x00     | Incr      | 32-bit   | 3 data transfers |
| 0x04, word 1 | 0x04     | Incr      | 32-bit   | 3 data transfers |
| 0x08, word 2 | 0x08     | Incr      | 32-bit   | 3 data transfers |
| 0x0C, word 3 | 0x0C     | Incr      | 32-bit   | 3 data transfers |
| 0x10, word 4 | 0x10     | Incr      | 32-bit   | 3 data transfers |
| 0x14, word 5 | 0x14     | Incr      | 32-bit   | 3 data transfers |

Table 8-19 Noncacheable LDM3, Noncacheable memory or cache disabled

| Address[4:0] | ARADDRRW | ARBURSTRW | ARSIZERW | ARLENRW          |
|--------------|----------|-----------|----------|------------------|
| 0x00, word 0 | 0x00     | Incr      | 64-bit   | 2 data transfers |
| 0x04, word 1 | 0x04     | Incr      | 64-bit   | 2 data transfers |
| 0x08, word 2 | 0x08     | Incr      | 64-bit   | 2 data transfers |
| 0x0C, word 3 | 0x0C     | Incr      | 64-bit   | 2 data transfers |
| 0x10, word 4 | 0x10     | Incr      | 64-bit   | 2 data transfers |
| 0x14, word 5 | 0x14     | Incr      | 64-bit   | 2 data transfers |

**Table 8-20 Noncacheable LDM3 from word 6, or 7**

| Address[4:0] | Operations                     |
|--------------|--------------------------------|
| 0x18, word 6 | LDM2 from 0x18 + LDR from 0x00 |
| 0x1C, word 7 | LDR from 0x1C + LDM2 from 0x00 |

### 8.5.7 Noncacheable LDM4

The values of **ARADDRRW**, **ARBURSTRW**, **ARSizerw**, and **ARLENrw** for Noncacheable LDM4s addressing words 0 to 4 are shown in:

- Table 8-21 for a load from Strongly Ordered or Device memory
- Table 8-22 for a load from Noncacheable memory or when the cache is disabled.

A Noncacheable LDM4 addressing words 5 to 7 is split into two operations as shown in Table 8-23 on page 8-24.

**Table 8-21 Noncacheable LDM4, Strongly Ordered or Device memory**

| Address[4:0] | ARADDRRW | ARBURSTRW | ARSIZERW | ARLENRW          |
|--------------|----------|-----------|----------|------------------|
| 0x00, word 0 | 0x00     | Incr      | 64-bit   | 2 data transfers |
| 0x04, word 1 | 0x04     | Incr      | 32-bit   | 4 data transfers |
| 0x08, word 2 | 0x08     | Incr      | 64-bit   | 2 data transfers |
| 0x0C, word 3 | 0x0C     | Incr      | 32-bit   | 4 data transfers |
| 0x10, word 4 | 0x10     | Incr      | 64-bit   | 2 data transfers |

**Table 8-22 Noncacheable LDM4, Noncacheable memory or cache disabled**

| Address[4:0] | ARADDRRW | ARBURSTRW | ARSIZERW | ARLENRW          |
|--------------|----------|-----------|----------|------------------|
| 0x00, word 0 | 0x00     | Incr      | 64-bit   | 2 data transfers |
| 0x04, word 1 | 0x04     | Incr      | 64-bit   | 3 data transfers |
| 0x08, word 2 | 0x08     | Incr      | 64-bit   | 2 data transfers |
| 0x0C, word 3 | 0x0C     | Incr      | 64-bit   | 3 data transfers |
| 0x10, word 4 | 0x10     | Incr      | 64-bit   | 2 data transfers |

Table 8-23 Noncacheable LDM4 from word 5, 6, or 7

| Address[4:0] | Operations                      |
|--------------|---------------------------------|
| 0x14, word 5 | LDM3 from 0x14 + LDR from 0x00  |
| 0x18, word 6 | LDM2 from 0x18 + LDM2 from 0x00 |
| 0x1C, word 7 | LDR from 0x1C + LDM3 from 0x00  |

8.5.8 Noncacheable LDM5

The values of **ARADDRRW**, **ARBURSTRW**, **ARSizerw**, and **ARLENrw** for Noncacheable LDM5s addressing words 0 to 3 are shown in:

- Table 8-24 for a load from Strongly Ordered or Device memory
- Table 8-25 for a load from Noncacheable memory or when the cache is disabled.

A Noncacheable LDM5 addressing words 4 to 7 is split into two operations as shown in Table 8-26 on page 8-25.

Table 8-24 Noncacheable LDM5, Strongly Ordered or Device memory

| Address[4:0] | ARADDRRW | ARBURSTRW | ARSIZERW | ARLENRW          |
|--------------|----------|-----------|----------|------------------|
| 0x00, word 0 | 0x00     | Incr      | 32-bit   | 5 data transfers |
| 0x04, word 1 | 0x04     | Incr      | 32-bit   | 5 data transfers |
| 0x08, word 2 | 0x08     | Incr      | 32-bit   | 5 data transfers |
| 0x0C, word 3 | 0x0C     | Incr      | 32-bit   | 5 data transfers |

Table 8-25 Noncacheable LDM5, Noncacheable memory or cache disabled

| Address[4:0] | ARADDRRW | ARBURSTRW | ARSIZERW | ARLENRW          |
|--------------|----------|-----------|----------|------------------|
| 0x00, word 0 | 0x00     | Incr      | 64-bit   | 3 data transfers |
| 0x04, word 1 | 0x04     | Incr      | 64-bit   | 3 data transfers |
| 0x08, word 2 | 0x08     | Incr      | 64-bit   | 3 data transfers |
| 0x0C, word 3 | 0x0C     | Incr      | 64-bit   | 3 data transfers |

**Table 8-26 Noncacheable LDM5 from word 4, 5, 6, or 7**

| Address[4:0] | Operations                      |
|--------------|---------------------------------|
| 0x10, word 4 | LDM4 from 0x10 + LDR from 0x00  |
| 0x14, word 5 | LDM3 from 0x14 + LDM2 from 0x00 |
| 0x18, word 6 | LDM2 from 0x18 + LDM3 from 0x00 |
| 0x1C, word 7 | LDR from 0x1C + LDM4 from 0x00  |

### 8.5.9 Noncacheable LDM6

The values of **ARADDRRW**, **ARBURSTRW**, **ARSIZERW**, and **ARLENRW** for Noncacheable LDM6s addressing words 0 to 2 are shown in:

- Table 8-27 for a load from Strongly Ordered or Device memory
- Table 8-28 for a load from Noncacheable memory or when the cache is disabled.

A Noncacheable LDM6 addressing words 3 to 7 is split into two operations as shown in Table 8-29 on page 8-26.

**Table 8-27 Noncacheable LDM6, Strongly Ordered or Device memory**

| Address[4:0] | ARADDRRW | ARBURSTRW | ARSIZERW | ARLENRW          |
|--------------|----------|-----------|----------|------------------|
| 0x00, word 0 | 0x00     | Incr      | 64-bit   | 3 data transfers |
| 0x04, word 1 | 0x04     | Incr      | 32-bit   | 6 data transfers |
| 0x08, word 2 | 0x08     | Incr      | 64-bit   | 3 data transfers |

**Table 8-28 Noncacheable LDM6, Noncacheable memory or cache disabled**

| Address[4:0] | ARADDRRW | ARBURSTRW | ARSIZERW | ARLENRW          |
|--------------|----------|-----------|----------|------------------|
| 0x00, word 0 | 0x00     | Incr      | 64-bit   | 3 data transfers |
| 0x04, word 1 | 0x04     | Incr      | 64-bit   | 4 data transfers |
| 0x08, word 2 | 0x08     | Incr      | 64-bit   | 3 data transfers |

Table 8-29 Noncacheable LDM6 from word 3, 4, 5, 6, or 7

| Address[4:0] | Operations                      |
|--------------|---------------------------------|
| 0x0C, word 3 | LDM5 from 0x0C + LDR from 0x00  |
| 0x10, word 4 | LDM4 from 0x10 + LDM2 from 0x00 |
| 0x14, word 5 | LDM3 from 0x14 + LDM3 from 0x00 |
| 0x18, word 6 | LDM2 from 0x18 + LDM4 from 0x00 |
| 0x1C, word 7 | LDR from 0x1C + LDM5 from 0x00  |

8.5.10 Noncacheable LDM7

- The values of **ARADDRRW**, **ARBURSTRW**, **ARSizerw**, and **ARLENrw** for Noncacheable LDM7s addressing word 0 or 1 are shown in:
- Table 8-30 for a load from Strongly Ordered or Device memory
  - Table 8-31 for a load from Noncacheable memory or when the cache is disabled.

A Noncacheable LDM7 addressing words 2 to 7 is split into two operations as shown in Table 8-32 on page 8-27.

Table 8-30 Noncacheable LDM7, Strongly Ordered or Device memory

| Address[4:0] | ARADDRRW | ARBURSTRW | ARSIZERW | ARLENRW          |
|--------------|----------|-----------|----------|------------------|
| 0x00, word 0 | 0x00     | Incr      | 32-bit   | 7 data transfers |
| 0x04, word 1 | 0x04     | Incr      | 32-bit   | 7 data transfers |

Table 8-31 Noncacheable LDM7, Noncacheable memory or cache disabled

| Address[4:0] | ARADDRRW | ARBURSTRW | ARSIZERW | ARLENRW          |
|--------------|----------|-----------|----------|------------------|
| 0x00, word 0 | 0x00     | Incr      | 64-bit   | 4 data transfers |
| 0x04, word 1 | 0x04     | Incr      | 64-bit   | 4 data transfers |

**Table 8-32 Noncacheable LDM7 from word 2, 3, 4, 5, 6, or 7**

| Address[4:0] | Operations                      |
|--------------|---------------------------------|
| 0x08, word 2 | LDM6 from 0x08 + LDR from 0x00  |
| 0x0C, word 3 | LDM5 from 0x0C + LDM2 from 0x00 |
| 0x10, word 4 | LDM4 from 0x10 + LDM3 from 0x00 |
| 0x14, word 5 | LDM3 from 0x14 + LDM4 from 0x00 |
| 0x18, word 6 | LDM2 from 0x18 + LDM5 from 0x00 |
| 0x1C, word 7 | LDR from 0x1C + LDM6 from 0x00  |

### 8.5.11 Noncacheable LDM8

Table 8-33 shows the values of **ARADDRRW**, **ARBURSTRW**, **ARSizerW**, and **ARLENRW** for a Noncacheable LDM8 addressing word 0.

A Noncacheable LDM8 addressing words 1 to 7 is split into two operations as shown in Table 8-34.

**Table 8-33 Noncacheable LDM8 from word 0**

| Address[4:0] | ARADDRRW | ARBURSTRW | ARSizerW | ARLENRW          |
|--------------|----------|-----------|----------|------------------|
| 0x00, word 0 | 0x00     | Incr      | 64-bit   | 4 data transfers |

**Table 8-34 Noncacheable LDM8 from word 1, 2, 3, 4, 5, 6, or 7**

| Address[4:0] | Operations                      |
|--------------|---------------------------------|
| 0x04, word 1 | LDM7 from 0x04 + LDR from 0x00  |
| 0x08, word 2 | LDM6 from 0x08 + LDM2 from 0x00 |
| 0x0C, word 3 | LDM5 from 0x0C + LDM3 from 0x00 |
| 0x10, word 4 | LDM4 from 0x10 + LDM4 from 0x00 |
| 0x14, word 5 | LDM3 from 0x14 + LDM5 from 0x00 |
| 0x18, word 6 | LDM2 from 0x18 + LDM6 from 0x00 |
| 0x1C, word 7 | LDR from 0x1C + LDM7 from 0x00  |

8.5.12 Noncacheable LDM9

A Noncacheable LDM9 is split into two operations as shown in Table 8-35.

Table 8-35 Noncacheable LDM9

| Address[4:0] | Operations                      |
|--------------|---------------------------------|
| 0x00, word 0 | LDM8 from 0x00 + LDR from 0x00  |
| 0x04, word 1 | LDM7 from 0x04 + LDM2 from 0x00 |
| 0x08, word 2 | LDM6 from 0x08 + LDM3 from 0x00 |
| 0x0C, word 3 | LDM5 from 0x0C + LDM4 from 0x00 |
| 0x10, word 4 | LDM4 from 0x10 + LDM5 from 0x00 |
| 0x14, word 5 | LDM3 from 0x14 + LDM6 from 0x00 |
| 0x18, word 6 | LDM2 from 0x18 + LDM7 from 0x00 |
| 0x1C, word 7 | LDR from 0x1C + LDM8 from 0x00  |

8.5.13 Noncacheable LDM10

A Noncacheable LDM10 is split into two or three operations as shown in Table 8-36.

Table 8-36 Noncacheable LDM10

| Address[4:0] | Operations                                     |
|--------------|------------------------------------------------|
| 0x00, word 0 | LDM8 from 0x00 + LDM2 from 0x00                |
| 0x04, word 1 | LDM7 from 0x04 + LDM3 from 0x00                |
| 0x08, word 2 | LDM6 from 0x08 + LDM4 from 0x00                |
| 0x0C, word 3 | LDM5 from 0x0C + LDM5 from 0x00                |
| 0x10, word 4 | LDM4 from 0x10 + LDM6 from 0x00                |
| 0x14, word 5 | LDM3 from 0x14 + LDM7 from 0x00                |
| 0x18, word 6 | LDM2 from 0x18 + LDM8 from 0x00                |
| 0x1C, word 7 | LDR from 0x1C + LDM8 from 0x00 + LDR from 0x00 |

### 8.5.14 Noncacheable LDM11

A Noncacheable LDM11 is split into two or three operations as shown in Table 8-37.

**Table 8-37 Noncacheable LDM11**

| Address[4:0] | Operations                                      |
|--------------|-------------------------------------------------|
| 0x00, word 0 | LDM8 from 0x00 + LDM3 from 0x00                 |
| 0x04, word 1 | LDM7 from 0x04 + LDM4 from 0x00                 |
| 0x08, word 2 | LDM6 from 0x08 + LDM5 from 0x00                 |
| 0x0C, word 3 | LDM5 from 0x0C + LDM6 from 0x00                 |
| 0x10, word 4 | LDM4 from 0x10 + LDM7 from 0x00                 |
| 0x14, word 5 | LDM3 from 0x14 + LDM8 from 0x00                 |
| 0x18, word 6 | LDM2 from 0x18 + LDM8 from 0x00 + LDR from 0x00 |
| 0x1C, word 7 | LDR from 0x1C + LDM8 from 0x00 + LDM2 from 0x00 |

### 8.5.15 Noncacheable LDM12

A Noncacheable LDM12 is split into two or three operations as shown in Table 8-38.

**Table 8-38 Noncacheable LDM12**

| Address[4:0] | Operations                                       |
|--------------|--------------------------------------------------|
| 0x00, word 0 | LDM8 from 0x00 + LDM4 from 0x00                  |
| 0x04, word 1 | LDM7 from 0x04 + LDM5 from 0x00                  |
| 0x08, word 2 | LDM6 from 0x08 + LDM6 from 0x00                  |
| 0x0C, word 3 | LDM5 from 0x0C + LDM7 from 0x00                  |
| 0x10, word 4 | LDM4 from 0x10 + LDM8 from 0x00                  |
| 0x14, word 5 | LDM3 from 0x14 + LDM8 from 0x00 + LDR from 0x00  |
| 0x18, word 6 | LDM2 from 0x18 + LDM8 from 0x00 + LDM2 from 0x00 |
| 0x1C, word 7 | LDR from 0x1C + LDM8 from 0x00 + LDM3 from 0x00  |

8.5.16 Noncacheable LDM13

A Noncacheable LDM13 is split into two or three operations as shown in Table 8-39.

Table 8-39 Noncacheable LDM13

| Address[4:0] | Operations                                       |
|--------------|--------------------------------------------------|
| 0x00, word 0 | LDM8 from 0x00 + LDM5 from 0x00                  |
| 0x04, word 1 | LDM7 from 0x04 + LDM6 from 0x00                  |
| 0x08, word 2 | LDM6 from 0x08 + LDM7 from 0x00                  |
| 0x0C, word 3 | LDM5 from 0x0C + LDM8 from 0x00                  |
| 0x10, word 4 | LDM4 from 0x10 + LDM8 from 0x00 + LDR from 0x00  |
| 0x14, word 5 | LDM3 from 0x14 + LDM8 from 0x00 + LDM2 from 0x00 |
| 0x18, word 6 | LDM2 from 0x18 + LDM8 from 0x00 + LDM3 from 0x00 |
| 0x1C, word 7 | LDR from 0x1C + LDM8 from 0x00 + LDM4 from 0x00  |

8.5.17 Noncacheable LDM14

A Noncacheable LDM14 is split into two or three operations as shown in Table 8-40.

Table 8-40 Noncacheable LDM14

| Address[4:0] | Operations                                       |
|--------------|--------------------------------------------------|
| 0x00, word 0 | LDM8 from 0x00 + LDM6 from 0x00                  |
| 0x04, word 1 | LDM7 from 0x04 + LDM7 from 0x00                  |
| 0x08, word 2 | LDM6 from 0x08 + LDM8 from 0x00                  |
| 0x0C, word 3 | LDM5 from 0x0C + LDM8 from 0x00 + LDR from 0x00  |
| 0x10, word 4 | LDM4 from 0x10 + LDM8 from 0x00 + LDM2 from 0x00 |
| 0x14, word 5 | LDM3 from 0x14 + LDM8 from 0x00 + LDM3 from 0x00 |
| 0x18, word 6 | LDM2 from 0x18 + LDM8 from 0x00 + LDM4 from 0x00 |
| 0x1C, word 7 | LDR from 0x1C + LDM8 from 0x00 + LDM5 from 0x00  |

### 8.5.18 Noncacheable LDM15

A Noncacheable LDM15 is split into two or three operations as shown in Table 8-41.

**Table 8-41 Noncacheable LDM15**

| Address[4:0] | Operations                                       |
|--------------|--------------------------------------------------|
| 0x00, word 0 | LDM8 from 0x00 + LDM7 from 0x00                  |
| 0x04, word 1 | LDM7 from 0x04 + LDM8 from 0x00                  |
| 0x08, word 2 | LDM6 from 0x08 + LDM8 from 0x00 + LDR from 0x00  |
| 0x0C, word 3 | LDM5 from 0x0C + LDM8 from 0x00 + LDM2 from 0x00 |
| 0x10, word 4 | LDM4 from 0x10 + LDM8 from 0x00 + LDM3 from 0x00 |
| 0x14, word 5 | LDM3 from 0x14 + LDM8 from 0x00 + LDM4 from 0x00 |
| 0x18, word 6 | LDM2 from 0x18 + LDM8 from 0x00 + LDM5 from 0x00 |
| 0x1C, word 7 | LDR from 0x1C + LDM8 from 0x00 + LDM6 from 0x00  |

### 8.5.19 Noncacheable LDM16

A Noncacheable LDM16 is split into two or three operations as shown in Table 8-41.

**Table 8-42 Noncacheable LDM16**

| Address[4:0] | Operations                                       |
|--------------|--------------------------------------------------|
| 0x00, word 0 | LDM8 from 0x00 + LDM8 from 0x00                  |
| 0x04, word 1 | LDM7 from 0x04 + LDM8 from 0x00 + LDR from 0x00  |
| 0x08, word 2 | LDM6 from 0x08 + LDM8 from 0x00 + LDM2 from 0x00 |
| 0x0C, word 3 | LDM5 from 0x0C + LDM8 from 0x00 + LDM3 from 0x00 |
| 0x10, word 4 | LDM4 from 0x10 + LDM8 from 0x00 + LDM4 from 0x00 |
| 0x14, word 5 | LDM3 from 0x14 + LDM8 from 0x00 + LDM5 from 0x00 |
| 0x18, word 6 | LDM2 from 0x18 + LDM8 from 0x00 + LDM6 from 0x00 |
| 0x1C, word 7 | LDR from 0x1C + LDM8 from 0x00 + LDM7 from 0x00  |

8.5.20 Half-line Write-Back

Table 8-43 shows the values of **AWADDRRW**, **AWBURSTRW**, **AWSIZERW**, and **AWLENRW** for half-line Write-Backs over the Data read/write interface.

Table 8-43 Half-line Write-Back

| Write address [4:0] | Description                                   | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW          |
|---------------------|-----------------------------------------------|----------|-----------|----------|------------------|
| 0x00-0x07           | Evicted cache line valid and lower half dirty | 0x00     | Incr      | 64-bit   | 2 data transfers |
|                     | Evicted cache line valid and upper half dirty | 0x10     | Incr      | 64-bit   | 2 data transfers |
| 0x08-0x0F           | Evicted cache line valid and lower half dirty | 0x08     | Wrap      | 64-bit   | 2 data transfers |
|                     | Evicted cache line valid and upper half dirty | 0x10     | Incr      | 64-bit   | 2 data transfers |
| 0x10-0x17           | Evicted cache line valid and lower half dirty | 0x00     | Incr      | 64-bit   | 2 data transfers |
|                     | Evicted cache line valid and upper half dirty | 0x10     | Incr      | 64-bit   | 2 data transfers |
| 0x18-0x1F           | Evicted cache line valid and lower half dirty | 0x00     | Incr      | 64-bit   | 2 data transfers |
|                     | Evicted cache line valid and upper half dirty | 0x18     | Wrap      | 64-bit   | 2 data transfers |

### 8.5.21 Full-line Write-Back

Table 8-44 lists the values of **AWADDRRW**, **AWBURSTRW**, **AWSIZERW**, and **AWLENRW** for full-line Write-Backs, evicted cache line valid and both halves dirty, over the Data read/write interface.

**Table 8-44 Full-line Write-Back**

| Write address [4:0] | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW          |
|---------------------|----------|-----------|----------|------------------|
| 0x00-0x07           | 0x00     | Incr      | 64-bit   | 4 data transfers |
| 0x08-0x0F           | 0x08     | Wrap      | 64-bit   | 4 data transfers |
| 0x10-0x17           | 0x10     | Wrap      | 64-bit   | 4 data transfers |
| 0x18-0x1F           | 0x18     | Wrap      | 64-bit   | 4 data transfers |

### 8.5.22 Cacheable Write-Through or Noncacheable STRB

Table 8-45 lists the values of **AWADDRRW**, **AWBURSTRW**, **AWSIZERW**, and **AWLENRW** for STRBs over the Data read/write interface.

**Table 8-45 Cacheable Write-Through or Noncacheable STRB**

| Address[4:0] | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW         | WSTRBRW    |
|--------------|----------|-----------|----------|-----------------|------------|
| 0x00, byte 0 | 0x00     | Incr      | 8-bit    | 1 data transfer | b0000 0001 |
| 0x01, byte 1 | 0x01     | Incr      | 8-bit    | 1 data transfer | b0000 0010 |
| 0x02, byte 2 | 0x02     | Incr      | 8-bit    | 1 data transfer | b0000 0100 |
| 0x03, byte 3 | 0x03     | Incr      | 8-bit    | 1 data transfer | b0000 1000 |
| 0x04, byte 4 | 0x04     | Incr      | 8-bit    | 1 data transfer | b0001 0000 |
| 0x05, byte 5 | 0x05     | Incr      | 8-bit    | 1 data transfer | b0010 0000 |
| 0x06, byte 6 | 0x06     | Incr      | 8-bit    | 1 data transfer | b0100 0000 |
| 0x07, byte 7 | 0x07     | Incr      | 8-bit    | 1 data transfer | b1000 0000 |

### 8.5.23 Cacheable Write-Through or Noncacheable STRH

Table 8-46 lists the values of **AWADDRRW**, **AWBURSTRW**, **AWSIZERW**, and **AWLENRW** for STRHs over the Data read/write interface.

**Table 8-46 Cacheable Write-Through or Noncacheable STRH**

| Address[4:0] | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW         | WSTRBRW    |
|--------------|----------|-----------|----------|-----------------|------------|
| 0x00, byte 0 | 0x00     | Incr      | 16-bit   | 1 data transfer | b0000 0011 |
| 0x01, byte 1 | 0x01     | Incr      | 32-bit   | 1 data transfer | b0000 0110 |
| 0x02, byte 2 | 0x02     | Incr      | 16-bit   | 1 data transfer | b0000 1100 |
| 0x03, byte 3 | 0x03     | Incr      | 8-bit    | 1 data transfer | b0000 1000 |
|              | 0x04     | Incr      | 8-bit    | 1 data transfer | b0001 0000 |
| 0x04, byte 4 | 0x04     | Incr      | 16-bit   | 1 data transfer | b0011 0000 |
| 0x05, byte 5 | 0x05     | Incr      | 32-bit   | 1 data transfer | b0110 0000 |
| 0x06, byte 6 | 0x06     | Incr      | 16-bit   | 1 data transfer | b1100 0000 |
| 0x07, byte 7 | 0x07     | Incr      | 8-bit    | 1 data transfer | b1000 0000 |
|              | 0x08     | Incr      | 8-bit    | 1 data transfer | b0000 0001 |

### 8.5.24 Cacheable Write-Through or Noncacheable STR or STM1

Table 8-47 lists the values of **AWADDRRW**, **AWBURSTRW**, **AWSIZERW**, and **AWLENRW** for STRs or STM1s over the Data read/write interface.

**Table 8-47 Cacheable Write-Through or Noncacheable STR or STM1**

| Address[4:0]         | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW         | WSTRBRW    |
|----------------------|----------|-----------|----------|-----------------|------------|
| 0x00, byte 0, word 0 | 0x00     | Incr      | 32-bit   | 1 data transfer | b0000 1111 |
| 0x01, byte 1         | 0x00     | Incr      | 32-bit   | 1 data transfer | b0000 1110 |
|                      | 0x04     | Incr      | 8-bit    | 1 data transfer | b0001 0000 |
| 0x02, byte 2         | 0x02     | Incr      | 16-bit   | 1 data transfer | b0000 1100 |
|                      | 0x04     | Incr      | 16-bit   | 1 data transfer | b0011 0000 |
| 0x03, byte 3         | 0x03     | Incr      | 8-bit    | 1 data transfer | b0000 1000 |
|                      | 0x04     | Incr      | 32-bit   | 1 data transfer | b0111 0000 |

**Table 8-47 Cacheable Write-Through or Noncacheable STR or STM1 (continued)**

| Address[4:0]         | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW         | WSTRBRW    |
|----------------------|----------|-----------|----------|-----------------|------------|
| 0x04, byte 4, word 1 | 0x04     | Incr      | 32-bit   | 1 data transfer | b1111 0000 |
| 0x05, byte 5         | 0x04     | Incr      | 32-bit   | 1 data transfer | b1110 0000 |
|                      | 0x08     | Incr      | 8-bit    | 1 data transfer | b0000 0001 |
| 0x06, byte 6         | 0x06     | Incr      | 16-bit   | 1 data transfer | b1100 0000 |
|                      | 0x08     | Incr      | 16-bit   | 1 data transfer | b0000 0011 |
| 0x07, byte 7         | 0x07     | Incr      | 8-bit    | 1 data transfer | b1000 0000 |
|                      | 0x08     | Incr      | 32-bit   | 1 data transfer | b0000 0111 |
| 0x08, byte 8, word 2 | 0x08     | Incr      | 32-bit   | 1 data transfer | b0000 1111 |
| 0x0C, word 3         | 0x0C     | Incr      | 32-bit   | 1 data transfer | b1111 0000 |
| 0x10, word 4         | 0x10     | Incr      | 32-bit   | 1 data transfer | b0000 1111 |
| 0x14, word 5         | 0x14     | Incr      | 32-bit   | 1 data transfer | b1111 0000 |
| 0x18, word 6         | 0x18     | Incr      | 32-bit   | 1 data transfer | b0000 1111 |
| 0x1C, word 7         | 0x1C     | Incr      | 32-bit   | 1 data transfer | b1111 0000 |

### 8.5.25 Cacheable Write-Through or Noncacheable STRD or STM2

Table 8-48 shows the values of **AWADDRRW**, **AWBURSTRW**, **AWSIZERW**, and **AWLENRW** for STRDs and STM2s to words 0 to 6 over the Data read/write interface.

An STRD or STM2 to word 7 is split into two operations as shown in Table 8-49 on page 8-36.

**Table 8-48 Cacheable Write-Through or Noncacheable STRD or STM2 to words 0 to 6**

| Address[4:0] | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW          | First WSTRBRW |
|--------------|----------|-----------|----------|------------------|---------------|
| 0x00, word 0 | 0x00     | Incr      | 64-bit   | 1 data transfer  | b1111 1111    |
| 0x04, word 1 | 0x04     | Incr      | 32-bit   | 2 data transfers | b1111 0000    |
| 0x08, word 2 | 0x08     | Incr      | 64-bit   | 1 data transfer  | b1111 1111    |
| 0x0C, word 3 | 0x0C     | Incr      | 32-bit   | 2 data transfers | b1111 0000    |

Table 8-48 Cacheable Write-Through or Noncacheable STRD or STM2 to words 0 to 6 (continued)

| Address[4:0] | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW          | First WSTRBRW |
|--------------|----------|-----------|----------|------------------|---------------|
| 0x10, word 4 | 0x10     | Incr      | 64-bit   | 1 data transfer  | b1111 1111    |
| 0x14, word 5 | 0x14     | Incr      | 32-bit   | 2 data transfers | b1111 0000    |
| 0x18, word 6 | 0x18     | Incr      | 64-bit   | 1 data transfer  | b1111 1111    |

Table 8-49 Cacheable Write-Through or Noncacheable STRD or STM2 to word 7

| Address[4:0] | Operations                |
|--------------|---------------------------|
| 0x1C         | STR to 0x1C + STR to 0x00 |

8.5.26 Cacheable Write-Through or Noncacheable STM3

Table 8-50 shows the values of **AWADDRRW**, **AWBURSTRW**, **AWSIZERW**, and **AWLENRW** for STM3s to words 0 to 5 over the Data read/write interface.

An STM3 to word 6 or 7 is split into two operations as shown in Table 8-51.

Table 8-50 Cacheable Write-Through or Noncacheable STM3 to words 0, 1, 2, 3, 4, or 5

| Address[4:0] | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW          | First WSTRBRW |
|--------------|----------|-----------|----------|------------------|---------------|
| 0x00, word 0 | 0x00     | Incr      | 32-bit   | 3 data transfers | b0000 1111    |
| 0x04, word 1 | 0x04     | Incr      | 32-bit   | 3 data transfers | b1111 0000    |
| 0x08, word 2 | 0x08     | Incr      | 32-bit   | 3 data transfers | b0000 1111    |
| 0x0C, word 3 | 0x0C     | Incr      | 32-bit   | 3 data transfers | b1111 0000    |
| 0x10, word 4 | 0x10     | Incr      | 32-bit   | 3 data transfers | b0000 1111    |
| 0x14, word 5 | 0x14     | Incr      | 32-bit   | 3 data transfers | b1111 0000    |

Table 8-51 Cacheable Write-Through or Noncacheable STM3 to words 6 or 7

| Address[4:0] | Operations                 |
|--------------|----------------------------|
| 0x18, word 6 | STM2 to 0x18 + STR to 0x00 |
| 0x1C, word 7 | STR to 0x1C + STM2 to 0x00 |

### 8.5.27 Cacheable Write-Through or Noncacheable STM4

Table 8-52 shows the values of **AWADDRRW**, **AWBURSTRW**, **AWSIZERW**, and **AWLENRW** for STM4s to words 0 to 4 over the Data read/write interface.

An STM4 to words 5 to 7 is split into two operations as shown in Table 8-53.

**Table 8-52 Cacheable Write-Through or Noncacheable STM4 to word 0, 1, 2, 3, or 4**

| Address[4:0] | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW          | First WSTRBRW |
|--------------|----------|-----------|----------|------------------|---------------|
| 0x00, word 0 | 0x00     | Incr      | 64-bit   | 2 data transfers | b1111 1111    |
| 0x04, word 1 | 0x04     | Incr      | 32-bit   | 4 data transfers | b11110000     |
| 0x08, word 2 | 0x08     | Incr      | 64-bit   | 2 data transfers | b11111111     |
| 0x0C, word 3 | 0x0C     | Incr      | 32-bit   | 4 data transfers | b11110000     |
| 0x10, word 4 | 0x10     | Incr      | 64-bit   | 2 data transfers | b11111111     |

**Table 8-53 Cacheable Write-Through or Noncacheable STM4 to word 5, 6, or 7**

| Address[4:0] | Operations                  |
|--------------|-----------------------------|
| 0x14, word 5 | STM3 to 0x14 + STR to 0x00  |
| 0x18, word 6 | STM2 to 0x18 + STM2 to 0x00 |
| 0x1C, word 7 | STR to 0x1C + STM3 to 0x00  |

### 8.5.28 Cacheable Write-Through or Noncacheable STM5

Table 8-54 shows the values of **AWADDRRW**, **AWBURSTRW**, **AWSIZERW**, and **AWLENRW** for STM5s to words 0 to 3 over the Data read/write interface.

An STM5 to words 4 to 7 is split into two operations as shown in Table 8-55 on page 8-38.

**Table 8-54 Cacheable Write-Through or Noncacheable STM5 to word 0, 1, 2, or 3**

| Address[4:0] | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW          | First WSTRBRW |
|--------------|----------|-----------|----------|------------------|---------------|
| 0x00, word 0 | 0x00     | Incr      | 32-bit   | 5 data transfers | b0000 1111    |

Table 8-54 Cacheable Write-Through or Noncacheable STM5 to word 0, 1, 2, or 3 (continued)

| Address[4:0] | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW          | First WSTRBRW |
|--------------|----------|-----------|----------|------------------|---------------|
| 0x04, word 1 | 0x04     | Incr      | 32-bit   | 5 data transfers | b1111 0000    |
| 0x08, word 2 | 0x08     | Incr      | 32-bit   | 5 data transfers | b0000 1111    |
| 0x0C, word 3 | 0x0C     | Incr      | 32-bit   | 5 data transfers | b1111 0000    |

Table 8-55 Cacheable Write-Through or Noncacheable STM5 to word 4, 5, 6, or 7

| Address[4:0] | Operations                  |
|--------------|-----------------------------|
| 0x10, word 4 | STM4 to 0x10 + STR to 0x00  |
| 0x14, word 5 | STM3 to 0x14 + STM2 to 0x00 |
| 0x18, word 6 | STM2 to 0x18 + STM3 to 0x00 |
| 0x1C, word 7 | STR to 0x1C + STM4 to 0x00  |

8.5.29 Cacheable Write-Through or Noncacheable STM6

Table 8-56 shows the values of **AWADDRRW**, **AWBURSTRW**, **AWSIZERW**, and **AWLENRW** for STM6s to words 0 to 2 over the Data read/write interface.

An STM6 to words 3 to 7 is split into two operations as shown in Table 8-57.

Table 8-56 Cacheable Write-Through or Noncacheable STM6 to word 0, 1, or 2

| Address[4:0] | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW          | First WSTRBRW |
|--------------|----------|-----------|----------|------------------|---------------|
| 0x00, word 0 | 0x00     | Incr      | 64-bit   | 3 data transfers | b1111 1111    |
| 0x04, word 1 | 0x04     | Incr      | 32-bit   | 6 data transfers | b1111 0000    |
| 0x08, word 2 | 0x08     | Incr      | 64-bit   | 3 data transfers | b1111 1111    |

Table 8-57 Cacheable Write-Through or Noncacheable STM6 to word 3, 4, 5, 6, or 7

| Address[4:0] | Operations                  |
|--------------|-----------------------------|
| 0x0C, word 3 | STM5 to 0x0C + STR to 0x00  |
| 0x10, word 4 | STM4 to 0x10 + STM2 to 0x00 |

**Table 8-57 Cacheable Write-Through or Noncacheable STM6 to word 3, 4, 5, 6, or 7**

| Address[4:0] | Operations                  |
|--------------|-----------------------------|
| 0x14, word 5 | STM3 to 0x14 + STM3 to 0x00 |
| 0x18, word 6 | STM2 to 0x18 + STM4 to 0x00 |
| 0x1C, word 7 | STR to 0x1C + STM5 to 0x00  |

8.5.30 Cacheable Write-Through or Noncacheable STM7

Table 8-58 shows the values of **AWADDRRW**, **AWBURSTRW**, **AWSIZERW**, and **AWLENRW** for STM7s to words 0 or 1 over the Data read/write interface.

An STM7 to words 2 to 7 is split into two operations as shown in Table 8-59.

Table 8-58 Cacheable Write-Through or Noncacheable STM7 to word 0 or 1

| Address[4:0] | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW          | First WSTRBRW |
|--------------|----------|-----------|----------|------------------|---------------|
| 0x00, word 0 | 0x00     | Incr      | 32-bit   | 7 data transfers | b0000 1111    |
| 0x04, word 1 | 0x04     | Incr      | 32-bit   | 7 data transfers | b1111 0000    |

Table 8-59 Cacheable Write-Through or Noncacheable STM7 to words 2 to 7

| Address[4:0] | Operations                  |
|--------------|-----------------------------|
| 0x08, word 2 | STM6 to 0x08 + STR to 0x00  |
| 0x0C, word 3 | STM5 to 0x0C + STM2 to 0x00 |
| 0x10, word 4 | STM4 to 0x10 + STM3 to 0x00 |
| 0x14, word 5 | STM3 to 0x14 + STM4 to 0x00 |
| 0x18, word 6 | STM2 to 0x18 + STM5 to 0x00 |
| 0x1C, word 7 | STR to 0x1C + STM6 to 0x00  |

8.5.31 Cacheable Write-Through or Noncacheable STM8

Table 8-60 shows the values of **AWADDRRW**, **AWBURSTRW**, **AWSIZERW**, and **AWLENRW** for an STM8 to word 0 over the Data read/write interface.

An STM8 to words 1 to 7 is split into two operations as shown in Table 8-61 on page 8-40.

Table 8-60 Cacheable Write-Through or Noncacheable STM8 to word 0

| Address[4:0] | AWADDRRW | AWBURSTRW | AWSIZERW | AWLENRW          | First WSTRBRW |
|--------------|----------|-----------|----------|------------------|---------------|
| 0x00, word 0 | 0x00     | Incr      | 64-bit   | 4 data transfers | b1111 1111    |

**Table 8-61 Cacheable Write-Through or Noncacheable STM8 to words 1 to 7**

| Address[4:0] | Operations                  |
|--------------|-----------------------------|
| 0x04, word 1 | STM7 to 0x04 + STR to 0x00  |
| 0x08, word 2 | STM6 to 0x08 + STM2 to 0x00 |
| 0x0C, word 3 | STM5 to 0x0C + STM3 to 0x00 |
| 0x10, word 4 | STM4 to 0x10 + STM4 to 0x00 |
| 0x14, word 5 | STM3 to 0x14 + STM5 to 0x00 |
| 0x18, word 6 | STM2 to 0x18 + STM6 to 0x00 |
| 0x1C, word 7 | STR to 0x1C + STM7 to 0x00  |

**8.5.32 Cacheable Write-Through or Noncacheable STM9**

An STM9 over the Data read/write interface is split into two operations as shown in Table 8-62.

**Table 8-62 Cacheable Write-Through or Noncacheable STM9**

| Address[4:0] | Operations                  |
|--------------|-----------------------------|
| 0x00, word 0 | STM8 to 0x00 + STR to 0x00  |
| 0x04, word 1 | STM7 to 0x04 + STM2 to 0x00 |
| 0x08, word 2 | STM6 to 0x08 + STM3 to 0x00 |
| 0x0C, word 3 | STM5 to 0x0C + STM4 to 0x00 |
| 0x10, word 4 | STM4 to 0x10 + STM5 to 0x00 |
| 0x14, word 5 | STM3 to 0x14 + STM6 to 0x00 |
| 0x18, word 6 | STM2 to 0x18 + STM7 to 0x00 |
| 0x1C, word 7 | STR to 0x1C + STM8 to 0x00  |

8.5.33 Cacheable Write-Through or Noncacheable STM10

An STM10 over the Data read/write interface is split into two or three operations as shown in Table 8-63.

Table 8-63 Cacheable Write-Through or Noncacheable STM10

| Address[4:0] | Operations                               |
|--------------|------------------------------------------|
| 0x00, word 0 | STM8 to 0x00 + STM2 to 0x00              |
| 0x04, word 1 | STM7 to 0x04 + STM3 to 0x00              |
| 0x08, word 2 | STM6 to 0x08 + STM4 to 0x00              |
| 0x0C, word 3 | STM5 to 0x0C + STM5 to 0x00              |
| 0x10, word 4 | STM4 to 0x10 + STM6 to 0x00              |
| 0x14, word 5 | STM3 to 0x14 + STM7 to 0x00              |
| 0x18, word 6 | STM2 to 0x18 + STM8 to 0x00              |
| 0x1C, word 7 | STR to 0x1C + STM8 to 0x00 + STR to 0x00 |

8.5.34 Cacheable Write-Through or Noncacheable STM11

An STM11 over the Data read/write interface is split into two or three operations as shown in Table 8-64.

Table 8-64 Cacheable Write-Through or Noncacheable STM11

| Address[4:0] | Operations                                |
|--------------|-------------------------------------------|
| 0x00, word 0 | STM8 to 0x00 + STM3 to 0x00               |
| 0x04, word 1 | STM7 to 0x04 + STM4 to 0x00               |
| 0x08, word 2 | STM6 to 0x08 + STM5 to 0x00               |
| 0x0C, word 3 | STM5 to 0x0C + STM6 to 0x00               |
| 0x10, word 4 | STM4 to 0x10 + STM7 to 0x00               |
| 0x14, word 5 | STM3 to 0x14 + STM8 to 0x00               |
| 0x18, word 6 | STM2 to 0x18 + STM8 to 0x00 + STR to 0x00 |
| 0x1C, word 7 | STR to 0x1C + STM8 to 0x00 + STM2 to 0x00 |

### 8.5.35 Cacheable Write-Through or Noncacheable STM12

An STM12 over the Data read/write interface is split into two or three operations as shown in Table 8-65.

**Table 8-65 Cacheable Write-Through or Noncacheable STM12**

| Address[4:0] | Operations                                 |
|--------------|--------------------------------------------|
| 0x00, word 0 | STM8 to 0x00 + STM4 to 0x00                |
| 0x04, word 1 | STM7 to 0x04 + STM5 to 0x00                |
| 0x08, word 2 | STM6 to 0x08 + STM6 to 0x00                |
| 0x0C, word 3 | STM5 to 0x0C + STM7 to 0x00                |
| 0x10, word 4 | STM4 to 0x10 + STM8 to 0x00                |
| 0x14, word 5 | STM3 to 0x14 + STM8 to 0x00 + STR to 0x00  |
| 0x18, word 6 | STM2 to 0x18 + STM8 to 0x00 + STM2 to 0x00 |
| 0x1C, word 7 | STR to 0x1C + STM8 to 0x00 + STM3 to 0x00  |

### 8.5.36 Cacheable Write-Through or Noncacheable STM13

An STM13 over the Data read/write interface is split into two or three operations as shown in Table 8-66.

**Table 8-66 Cacheable Write-Through or Noncacheable STM13**

| Address[4:0] | Operations                                 |
|--------------|--------------------------------------------|
| 0x00, word 0 | STM8 to 0x00 + STM5 to 0x00                |
| 0x04, word 1 | STM7 to 0x04 + STM6 to 0x00                |
| 0x08, word 2 | STM6 to 0x08 + STM7 to 0x00                |
| 0x0C, word 3 | STM5 to 0x0C + STM8 to 0x00                |
| 0x10, word 4 | STM4 to 0x10 + STM8 to 0x00 + STR to 0x00  |
| 0x14, word 5 | STM3 to 0x14 + STM8 to 0x00 + STM2 to 0x00 |
| 0x18, word 6 | STM2 to 0x18 + STM8 to 0x00 + STM3 to 0x00 |
| 0x1C, word 7 | STR to 0x1C + STM8 to 0x00 + STM4 to 0x00  |

8.5.37 Cacheable Write-Through or Noncacheable STM14

An STM14 over the Data read/write interface is split into two or three operations as shown in Table 8-67.

Table 8-67 Cacheable Write-Through or Noncacheable STM14

| Address[4:0] | Operations                                 |
|--------------|--------------------------------------------|
| 0x00, word 0 | STM8 to 0x00 + STM6 to 0x00                |
| 0x04, word 1 | STM7 to 0x04 + STM7 to 0x00                |
| 0x08, word 2 | STM6 to 0x08 + STM8 to 0x00                |
| 0x0C, word 3 | STM5 to 0x0C + STM8 to 0x00 + STR to 0x00  |
| 0x10, word 4 | STM4 to 0x10 + STM8 to 0x00 + STM2 to 0x00 |
| 0x14, word 5 | STM3 to 0x14 + STM8 to 0x00 + STM3 to 0x00 |
| 0x18, word 6 | STM2 to 0x18 + STM8 to 0x00 + STM4 to 0x00 |
| 0x1C, word 7 | STR to 0x1C + STM8 to 0x00 + STM5 to 0x00  |

8.5.38 Cacheable Write-Through or Noncacheable STM15

An STM15 over the Data read/write interface is split into two or three operations as shown in Table 8-68.

Table 8-68 Cacheable Write-Through or Noncacheable STM15

| Address[4:0] | Operations                                 |
|--------------|--------------------------------------------|
| 0x00, word 0 | STM8 to 0x00 + STM7 to 0x00                |
| 0x04, word 1 | STM7 to 0x04 + STM8 to 0x00                |
| 0x08, word 2 | STM6 to 0x08 + STM8 to 0x00 + STR to 0x00  |
| 0x0C, word 3 | STM5 to 0x0C + STM8 to 0x00 + STM2 to 0x00 |
| 0x10, word 4 | STM4 to 0x10 + STM8 to 0x00 + STM3 to 0x00 |
| 0x14, word 5 | STM3 to 0x14 + STM8 to 0x00 + STM4 to 0x00 |
| 0x18, word 6 | STM2 to 0x18 + STM8 to 0x00 + STM5 to 0x00 |
| 0x1C, word 7 | STR to 0x1C + STM8 to 0x00 + STM6 to 0x00  |

8.5.39 Cacheable Write-Through or Noncacheable STM16

An STM15 over the Data read/write interface is split into two or three operations as shown in Table 8-69.

Table 8-69 Cacheable Write-Through or Noncacheable STM16

| Address[4:0] | Operations                                 |
|--------------|--------------------------------------------|
| 0x00, word 0 | STM8 to 0x00 + STM8 to 0x00                |
| 0x04, word 1 | STM7 to 0x04 + STM8 to 0x00 + STR to 0x00  |
| 0x08, word 2 | STM6 to 0x08 + STM8 to 0x00 + STM2 to 0x00 |
| 0x0C, word 3 | STM5 to 0x0C + STM8 to 0x00 + STM3 to 0x00 |
| 0x10, word 4 | STM4 to 0x10 + STM8 to 0x00 + STM4 to 0x00 |
| 0x14, word 5 | STM3 to 0x14 + STM8 to 0x00 + STM5 to 0x00 |
| 0x18, word 6 | STM2 to 0x18 + STM8 to 0x00 + STM6 to 0x00 |
| 0x1C, word 7 | STR to 0x1C + STM8 to 0x00 + STM7 to 0x00  |

8.6 Peripheral interface transfers

The tables in this section describe the Peripheral interface behavior for reads and writes for the following interface signals:

- **AxADDRP[31:0]**
- **AxBURSTP[1:0]**
- **AxSIZEP[2:0]**
- **AxLENP[3:0]**
- **WSTRBP[3:0]**, for write accesses.

See the *AMBA AXI Protocol Specification* for details of the other AXI signals.

Table 8-70 lists the values of **AxADDRP**, **AxBURSTP**, **AxSIZEP**, **AxLENP**, and **WSTRBP** for example Peripheral interface reads and writes.

Table 8-70 Example Peripheral interface reads and writes

| Example transfer,<br>read or write | AxADDRP | AxBURSTP | AxSIZEP | AxLENP           | WSTRBP |
|------------------------------------|---------|----------|---------|------------------|--------|
| Words 0-7                          | 0x00    | Incr     | 32-bit  | 2 data transfers | b1111  |
|                                    | 0x04    |          |         |                  | b1111  |
|                                    | 0x08    | Incr     | 32-bit  | 2 data transfers | b1111  |
|                                    | 0x0C    |          |         |                  | b1111  |
|                                    | 0x10    | Incr     | 32-bit  | 2 data transfers | b1111  |
|                                    | 0x14    |          |         |                  | b1111  |
|                                    | 0x18    | Incr     | 32-bit  | 2 data transfers | b1111  |
|                                    | 0x1C    |          |         |                  | b1111  |
| Words 0-3                          | 0x00    | Incr     | 32-bit  | 2 data transfers | b1111  |
|                                    | 0x04    |          |         |                  | b1111  |
|                                    | 0x08    | Incr     | 32-bit  |                  | b1111  |
|                                    | 0x0C    |          |         |                  | b1111  |
| Words 0-2                          | 0x00    | Incr     | 32-bit  | 2 data transfers | b1111  |
|                                    | 0x04    |          |         |                  | b1111  |
|                                    | 0x08    | Incr     | 32-bit  | 1 data transfer  | b1111  |

Table 8-70 Example Peripheral interface reads and writes (continued)

| Example transfer,<br>read or write | AxADDRP | AxBURSTP | AxSIZEP | AxLENP           | WSTRBP |
|------------------------------------|---------|----------|---------|------------------|--------|
| Words 0-1                          | 0x00    | Incr     | 32-bit  | 2 data transfers | b1111  |
|                                    | 0x04    |          |         |                  | b1111  |
| Word 2                             | 0x08    | Incr     | 32-bit  | 1 data transfer  | b1111  |
| Word 0, bytes 0 and 1              | 0x00    | Incr     | 16-bit  | 1 data transfer  | b0011  |
| Word 1, bytes 2 and 3              | 0x06    | Incr     | 16-bit  | 1 data transfer  | b1100  |
| Word 2, byte 3                     | 0x0B    | Incr     | 8-bit   | 1 data transfer  | b1000  |

The peripheral port can only do incrementing bursts of 2 data transfers maximum. It does not support unaligned accesses.

# 8.7 Endianness

You can configure the processor to operate in one of three endianness modes using the U, B, and E bits of the CP15 c1 Control Register. Table 8-71 shows this. See *Mixed-endian access support* on page 6-22 for more information.

Table 8-71 Endianness configuration

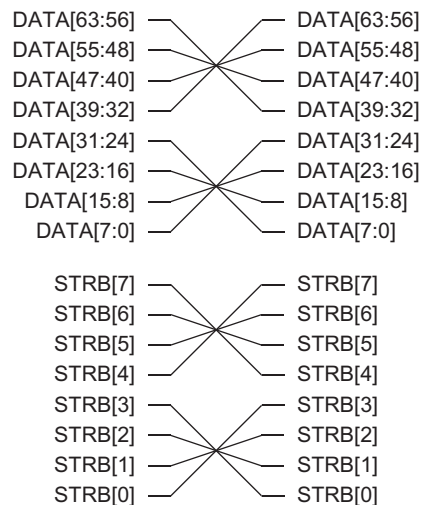

| U | B | E | Instruction<br>endianness | Data<br>endianness | Description                                                                            |
|---|---|---|---------------------------|--------------------|----------------------------------------------------------------------------------------|
| 0 | 0 | x | LE                        | LE                 | Little-endian.                                                                         |
| 1 | 0 | 0 |                           |                    |                                                                                        |
| 0 | 1 | x | BE-32                     | BE-32              | Big-endian 32-bit word-invariant.                                                      |
| 1 | 1 | 0 |                           |                    |                                                                                        |
| 1 | 0 | 1 | LE                        | BE-8 x             | Mixed endian configuration. Instruction little-endian, data big-endian byte-invariant. |

BE-8 refers to byte-invariant big-endian configuration on 16-bit, halfword, and 32-bit, word, quantities only.

Even if the data port is 64-bit wide, the accesses issued on this ports still have to be considered as two 32-bit accesses in parallel. The BE-8 configuration does not apply to the 64-bit data but on the two 32-bit words forming these 64-bit data.

The AXI protocol does not support 32-bit word-invariant big-endian, BE-32, accesses. Therefore, in this configuration the processor issues byte-invariant big-endian, BE-8, accesses on the four ports by swizzling the byte lanes and the byte strobes as Figure 8-4 on page 8-48 shows.

**Figure 8-4 Swizzling of data and strobes in BE-32 big-endian configuration**

**Note**

If you want to configure the processor for BE-32 mode, ARM strongly recommends that you use the **BIGENDINIT** and **UBITINIT** input pins. See *c1, Control Register* on page 3-46 bit [7].

## 8.8 Locked access

The AXI protocol specifies that, when a locked transaction occurs, the master must follow the locked transaction with an unlocked transaction to remove the lock of the interconnect. For ARM1156T2F-S processors, this implies that, in the case of an abort received on the read part of a SWP instruction, the Peripheral port or Data port issues a dummy write access with all byte strobes LOW at the same address as the read access and with **AWLOCK** = 00, normal transaction.

# Chapter 9

## Clocking and Resets

This chapter describes the clocking and reset options available for ARM1156T2F-S processors. It contains the following sections:

- *ARM1156T2F-S clocking* on page 9-2
- *Reset* on page 9-3
- *Reset modes* on page 9-4.

## 9.1 ARM1156T2F-S clocking

The ARM1156T2F-S processor has two functional clock inputs. Externally to the processor, you must connect together **CLKIN** and **FREECLKIN**.

For details on how the clock regions are implemented, see *ARM1156T2F-S and ARM1156T2-S Implementation Guide*.

For the purposes of this chapter, you can ignore **FREECLKIN**.

All clocks can be stopped indefinitely without loss of state.

You can preconfigure the ARM1156T2F-S processor so that each clock region operates synchronously to the core clock region.

## 9.2 Reset

The ARM1156T2F-S processor has the following reset inputs:

|                   |                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>nRESETIN</b>   | This signal is the main processor reset that initializes the majority of the ARM1156T2F-S logic.                                    |
| <b>DBGnTRST</b>   | This signal is the DBGTAP reset.                                                                                                    |
| <b>nPORESETIN</b> | This signal is the power-on reset that initializes the CP14 debug logic. See <i>CP14 registers reset</i> on page 13-24 for details. |

All of these are active LOW signals that reset logic in the ARM1156T2F-S processor. You must take care when designing the logic to drive these reset signals.

9.3 Reset modes

The reset signals present in the ARM1156T2F-S processor design to enable you to reset different parts of the design independently. The reset signals, and the combinations and possible applications that you can use them in, are shown in Table 9-1.

Table 9-1 Reset modes

| Reset mode      | nRESETIN | DBGnTRST | nPORESETIN | Application                                                                |
|-----------------|----------|----------|------------|----------------------------------------------------------------------------|
| Power-on reset  | 0        | x        | 0          | Reset at power up, full system reset.<br>Hard reset or cold reset.         |
| Processor reset | 0        | x        | 1          | Reset of processor core only, watchdog<br>reset. Soft reset or warm reset. |
| DBGTAP reset    | 1        | 0        | 1          | Reset of DBGTAP logic.                                                     |
| Normal          | 1        | x        | 1          | Normal run mode.                                                           |

Note

If **nRESETIN** is set to 1 and **nPORESETIN** is set to 0 the behavior is architecturally Unpredictable.

9.3.1 Power-on reset

You must apply power-on or *cold* reset to the ARM1156T2F-S processor when power is first applied to the system. In the case of power-on reset, the leading (falling) edge of the reset signals, **nRESETIN** and **nPORESETIN**, does not have to be synchronous to **CLKIN**. Because the **nRESETIN** and **nPORESETIN** signals are synchronized within the ARM1156T2F-S processor, you do not have to synchronize these signals. Figure 9-1 shows the application of power-on reset.

Figure 9-1 Power-on reset

It is recommended that you assert the reset signals for at least three **CLKIN** cycles to ensure correct reset behavior. Adopting a three-cycle reset eases the integration of other ARM parts into the system, for example, ARM9TDMI-based designs.

It is not necessary to assert **DBGnTRST** on power-up.

### 9.3.2 Processor reset

A processor or *warm* reset initializes the majority of the ARM1156T2F-S processor, excluding the ARM1156T2F-S DBGTAP controller and the EmbeddedICE-RT logic. Processor reset is typically used for resetting a system that has been operating for some time, for example, watchdog reset.

Because the **nRESETIN** signal is synchronized within the ARM1156T2F-S processor, you do not have to synchronize this signal.

### 9.3.3 DBGTAP reset

DBGTAP reset initializes the state of the ARM1156T2F-S DBGTAP controller. DBGTAP reset is typically used by the RealView™ ICE module for hot connection of a debugger to a system.

DBGTAP reset enables initialization of the DBGTAP controller without affecting the normal operation of the ARM1156T2F-S processor.

Because the **DBGnTRST** signal is synchronized within the ARM1156T2F-S processor, you do not have to synchronize this signal.

### 9.3.4 Normal operation

During normal operation, neither processor reset nor power-on reset is asserted. If the DBGTAP port is not being used, the value of **DBGnTRST** does not matter.

# Chapter 10

## Power Control

This chapter describes the ARM1156T2F-S power control functions. It contains the following sections:

- *About power control* on page 10-2
- *Power management* on page 10-3.

## 10.1 About power control

The features of the ARM1156T2F-S processor that improve energy efficiency include:

- accurate branch and return prediction, reducing the number of incorrect instruction fetch and decode operations
- use of physically addressed caches, which reduces the number of cache flushes and refills, saving energy in the system
- the caches use sequential access information to reduce the number of accesses to the Tag RAMs and to unwanted Data RAMs.

In the ARM1156T2F-S processor extensive use is also made of gated clocks and gates to disable inputs to unused functional blocks. Only the logic actively in use to perform a calculation consumes any dynamic power.

## 10.2 Power management

ARM1156T2F-S processors support three levels of power management:

- *Run mode*
- *Standby mode*
- *Shutdown mode* on page 10-4
- plus partial support for a fourth level, *Dormant mode* on page 10-4.

### 10.2.1 Run mode

Run mode is the normal mode of operation in which all of the functionality of the processor is available.

### 10.2.2 Standby mode

Standby mode disables most of the clocks of the device, while keeping the design powered up. This reduces the power drawn to the static leakage current, plus a tiny clock power overhead required to enable the device to wake up from the standby mode.

The transition from Standby mode to Run mode is caused by the either:

- arrival of an interrupt, whether masked or unmasked
- a debug request, only when debug is enabled
- reset.

The debug request can be generated by an externally generated debug request, using the **EDBGRQ** pin on the ARM1156T2F-S processor, or from a Debug Halt instruction issued to the ARM1156T2F-S processor through the debug scan chains.

Entry into Standby Mode is performed by executing the Wait For Interrupt CP15 operation. To ensure that the memory system is not affected by the entry into the standby mode, the following operations are performed:

- A Drain Write Buffer operation ensures that all explicit memory accesses occurring in program order before the Wait For Interrupt have completed. This avoids any possible deadlocks that could be caused in a system where memory access triggers or enables an interrupt that the core is waiting for.
- Any other memory accesses that have been started at the time that the Wait For Interrupt instruction is executed are completed as normal. This ensures that the level two memory system does not see any disruption caused by the Wait For Interrupt.

Systems using the VIC interface must ensure that the VIC is not masking any interrupts that are required for restarting the ARM1156T2F-S processor when in this mode of operation.

After the processor clocks have been stopped the signal **STANDBYWFI** is asserted to indicate that the ARM1156T2F-S processor is in Standby mode.

### 10.2.3 Shutdown mode

Shutdown mode has the entire device powered down, and you must externally save all state, including cache and TCM state. The processor is returned to Run mode by asserting and deasserting **nRESET**. This state saving is performed with interrupts disabled, and finishes with a Drain Write Buffer operation. When all the state of the ARM1156T2F-S processor is saved the ARM1156T2F-S processor executes a Wait For Interrupt instruction. The signal **STANDBYWFI** is asserted to indicate that the processor can enter Shutdown mode.

### 10.2.4 Dormant mode

Dormant mode enables the core to be powered down, leaving the caches and the *Tightly-Coupled Memory* (TCM) powered up and maintaining their state.

The software visibility of the Valid bits is provided to enable an implementation to be extended for Dormant mode, but some hardware modification of the RAM blocks during implementation to include an input clamp is required for the full implementation of Dormant mode.

#### Considerations for Dormant mode

Dormant mode is partially supported on ARM1156T2F-S processors, because care is required in implementing this on a standard synthesizable flow. The RAM blocks that are to remain powered up must be implemented on a separate power region, and there is a requirement to clamp all of the inputs to the RAMs to a known logic level (with the chip enable being held inactive). This clamping is not implemented in gates as part of the default synthesis flow because it contributes to a tight critical path.

Designers wanting to implement Dormant mode must add these clamps around the RAMs, either as explicit gates in the RAM power region, or as pull-down transistors that clamp the values while the core is powered down. The RAM blocks that must remain powered up in Dormant mode, if it is implemented, are:

- all Data RAMs associated with the cache and TCMs
- all Tag RAMs associated with the cache
- all Valid RAMs and Dirty RAMs associated with the cache.

Before entering Dormant mode, the state of the ARM1156T2F-S processor, excluding the contents of the RAMs that remain powered up in dormant mode, must be saved to external memory. These state saving operations must ensure that the following occur:

- All ARM registers, including CPSR and SPSR registers are saved.
- All CP15 registers are saved.
- All VFP registers are saved if the VFP contains defined state.
- All debug-related state is saved.
- The Master Valid bits for the cache are saved. For more details, see *Access to the cache valid bits*. These are accessed using CP15 register c15 as described in *c15, Instruction Cache Master Valid Register* on page 3-97 and *c15, Data Cache Master Valid Register* on page 3-97.
- A Drain Write Buffer instruction is executed to ensure that all state saving has been completed.  
A Wait For Interrupt CP15 operation is then executed, enabling the signal **STANDBYWFI** to indicate that the ARM1156T2F-S processor can enter Dormant mode.
- On entry into Dormant mode, the Reset signal to the ARM1156T2F-S processor must be asserted by the external power control mechanism.

To initiate the transition from Dormant mode to Run mode the external power controller must detect a request. When the request is received, the external power controller must assert and deassert the **nRESET** signal to the ARM1156T2F-S processor until the power to the processor is restored. When power has been restored the core leaves reset and, by interrogating the external power control, can determine that the saved state must be restored.

### 10.2.5 Access to the cache valid bits

The cache master valid bits are used to provide the ability to mask the valid bits held in the valid RAM for the cache. By doing this, a single cycle invalidation of the cache can be performed without requiring special resettable RAM cells. The number of master valid bits is a function of the cache size. There are 64 Cache master valid bits for a 16Kbyte cache, and the number of bits scales linearly with cache size. The maximum number of 32-bit registers required for the largest cache size (64K) is 8. The registers fill from the LSB of the lowest numbered register upwards with these valid bits.

Unimplemented valid bits are Unpredictable for reads and Should Be Zero or Preserved (SBZP) for writes.

Modifying the values of the valid bits using this mechanism can have Unpredictable effects. The intended usage is for these registers only to be written while the cache is disabled, and the values to be written are the values that were previously read out.

For the instructions that access the cache valid bits see *c15, Instruction Cache Master Valid Register* on page 3-97 and *c15, Data Cache Master Valid Register* on page 3-97

## 10.2.6 Communication to the Power Management Controller

The powering up and powering down of the processor can be controlled by a *Power Management Controller* (PMC). The communication mechanism between the ARM1156T2F-S processor and the PMC is a memory-mapped controller, which is accessed by the processor performing Strongly-Ordered accesses to it.

The **STANDBYWFI** signal from the ARM1156T2F-S processor informs the PMC which powerdown mode to be in.

The **STANDBYWFI** signal can also be used to signal that the ARM1156T2F-S processor is ready to have its power state changed. **STANDBYWFI** is asserted in response to a Wait For Interrupt operation.

# Chapter 11

## Coprocessor Interface

This chapter describes the ARM1156T2F-S coprocessor interface. It contains the following sections:

- *About the coprocessor interface* on page 11-2
- *Coprocessor pipeline* on page 11-3
- *Token queue management* on page 11-10
- *Token queues* on page 11-14
- *Data transfer* on page 11-18
- *Operations* on page 11-23
- *Multiple coprocessors* on page 11-26.

## 11.1 About the coprocessor interface

The processor connects to on-chip coprocessors through an external coprocessor interface. All types of coprocessor instruction are supported.

The ARM instruction set supports the connection of 16 coprocessors, numbered 0-15, to an ARM processor. In ARM1156T2F-S processors, the following coprocessor numbers are reserved:

|             |                 |
|-------------|-----------------|
| <b>CP10</b> | VFP control     |
| <b>CP11</b> | VFP control     |
| <b>CP14</b> | Debug           |
| <b>CP15</b> | System control. |

You can use CP0-9, CP12, and CP13 for your own external coprocessors.

The ARM1156T2F-S processor is designed to pass instructions to several coprocessors and exchange data with them. These coprocessors are intended to run in step with the core and are pipelined in a similar way to the core. Instructions are passed out of the Fetch stage of the core pipeline to the coprocessor and decoded. The decoded instruction is passed down its own pipeline. Coprocessor instructions can be canceled by the core if a condition code fails, or the entire coprocessor pipeline can be flushed in the event of a mispredicted branch. Load and store data are also required to pass between the core *Logic Store Unit* (LSU) and the coprocessor pipeline.

The coprocessor interface operates over a two-cycle delay. Any signal passing from the core to the coprocessor, or from the coprocessor to the core, is given a whole clock cycle to propagate from one to the other. This means that a signal crossing the interface is clocked out of a register on one side of the interface and clocked directly into another register on the other side. No combinatorial process must intervene. This constraint exists because the core and coprocessor can be placed a considerable distance apart and generous timing margins are necessary to cover signal propagation times. This delay in signal propagation makes it difficult to maintain pipeline synchronization, ruling out a tightly-coupled synchronization method.

ARM1156T2F-S processors implement a token-based pipeline synchronization method that permits some slack between the two pipelines, while ensuring that the pipelines are correctly aligned for crucial transfers of information.

## 11.2 Coprocessor pipeline

The coprocessor interface achieves loose synchronization between the two pipelines by exchanging tokens from one pipeline to the other. These tokens pass down queues between the pipelines and can carry additional information. In most cases the primary purpose of the queue is to carry information about the instruction being processed, or to inform one pipeline of events occurring in the other.

Tokens are generated whenever a coprocessor instruction passes out of a pipeline stage associated with a queue into the next stage. These tokens are picked up by the partner stage in the other pipeline, and used to enable the corresponding instruction in that stage to move on. The movement of coprocessor instructions down each pipeline is matched exactly by the movement of tokens along the various queues that connect the pipelines.

If a pipeline stage has no associated queue, the instruction contained within it moves on in the normal way. The coprocessor interface is data-driven rather than control-driven.

### 11.2.1 Coprocessor instructions

Each coprocessor can only execute a subset of all possible coprocessor instructions. Coprocessors reject those instructions they cannot handle. Table 11-1 lists all the coprocessor instructions supported by ARM1156T2F-S processors and gives a brief description of each. For more details of coprocessor instructions, see the *ARM Architecture Reference Manual*.

**Table 11-1 Coprocessor instructions**

| Instruction | Data transfer | Vectored | Description                                                                                     |
|-------------|---------------|----------|-------------------------------------------------------------------------------------------------|
| CDP         | None          | No       | Processes information already held within the coprocessor                                       |
| MRC         | Store         | No       | Transfers information from the coprocessor to the core registers                                |
| MCR         | Load          | No       | Transfers information from the core registers to the coprocessor                                |
| MRRC        | Store         | No       | Transfers information from the coprocessor to a pair of registers in the core                   |
| MCRR        | Load          | No       | Transfers information from a pair of registers in the core to the coprocessor                   |
| STC         | Store         | Yes      | Transfers information from the coprocessor to memory and might be iterated to transfer a vector |
| LDC         | Load          | Yes      | Transfers information from memory to the coprocessor and might be iterated to transfer a vector |

The coprocessor instructions fall into three groups:

- loads
- stores
- processing instructions.

The load and store instructions enable information to pass between the core and the coprocessor. Some of them might be vectored. This enables several values to be transferred in a single instruction. This typically involves the transfer of several words of data between a set of registers in the coprocessor and a contiguous set of locations in memory.

Other instructions, for example MCR and MRC, transfer data between core and coprocessor registers. The CDP instruction controls the execution of a specified operation on data already held within the coprocessor, writing the result back into a coprocessor register, or changing the state of the coprocessor in some other way. Opcode fields within the CDP instruction determine which operation is to be carried out.

The core pipeline handles both core and coprocessor instructions. The coprocessor, on the other hand, only deals with coprocessor instructions, so the coprocessor pipeline is likely to be empty for most of the time.

## 11.2.2 Coprocessor control

The coprocessor communicates with the core using several signals. Most of these signals control the synchronizing queues that connect the coprocessor pipeline to the core pipeline. The signals used for general coprocessor control are shown in Table 11-2.

**Table 11-2 Coprocessor control signals**

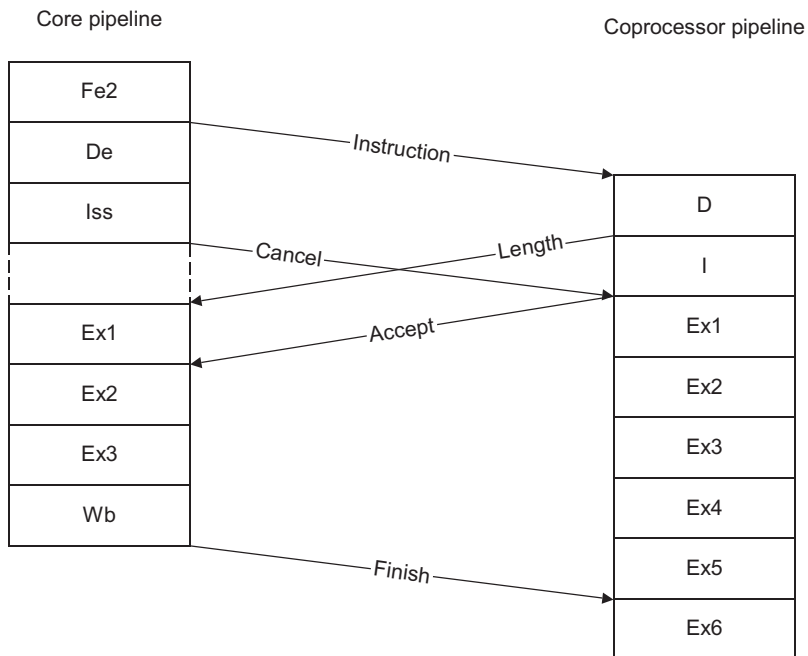

| Signal             | Description                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CLKIN</b>       | This is the clock signal from the core.                                                                                                                              |
| <b>RESET</b>       | This is the reset signal from the core.                                                                                                                              |
| <b>ACPNUM[3:0]</b> | This is the fixed number assigned to the coprocessor, and is in the range 0-13. Coprocessor numbers 10, 11, 14, and 15 are reserved for system control coprocessors. |
| <b>ACPENABLE</b>   | When set, enables the coprocessor to respond to signals from the core.                                                                                               |
| <b>ACPPRIV</b>     | When asserted, indicates that the core is in privileged mode. This might affect the execution of certain coprocessor instructions.                                   |

### 11.2.3 Pipeline synchronization

Figure 11-1 shows an outline of the core and coprocessor pipelines and the synchronizing queues that communicates between them. Each queue is implemented as a very short *First In First Out* (FIFO) buffer.

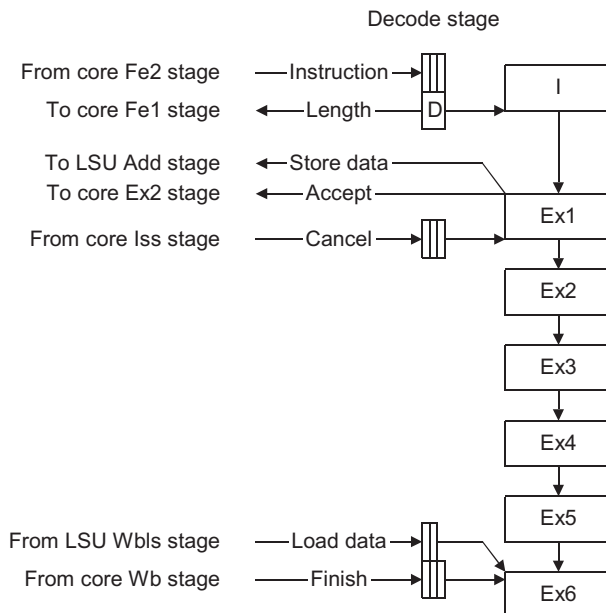

No explicit flow control is required for the queues, because the pipeline lengths between the queues limits the number of items any queue can hold at any time. The geometry used means that only three slots are required in each queue.

The only status information required is a flag to indicate when the queue is empty. This is monitored by the receiving end of the queue, and determines if the associated pipeline stage can move on. Any information carried by the queue can also be read and acted upon at the same time.

**Figure 11-1 Core and coprocessor pipelines**

Figure 11-2 on page 11-6 shows more information about the pipeline and the queues maintained by the coprocessor.

**Figure 11-2 Coprocessor pipeline and queues**

The instruction queue incorporates the instruction decoder and returns the length to the Ex1 stage of the core, using the length queue, which is maintained by the core. The coprocessor I stage sends a token to the core Ex2 stage through the accept queue, which is also maintained by the core. This token indicates to the core if the coprocessor is accepting the instruction in its I stage, or bouncing it.

The core can cancel an instruction currently in the coprocessor Ex1 stage by sending a signal with the token passed down the cancel queue. When a coprocessor instruction reads the Ex6 stage it might retire. How it retires depends on the instruction:

- Load instructions retire when they find load data available in the load data queue, see *Loads* on page 11-19
- Store instructions retire as soon as they leave the Ex1 stage, and are removed from the pipeline, see *Stores* on page 11-21
- CDP instructions retire when they read a token passed by the core down the finish queue.

Data transfer uses the load data and store data queues, which are shown in Figure 11-2 and explained in *Data transfer* on page 11-18.

### 11.2.4 Pipeline control

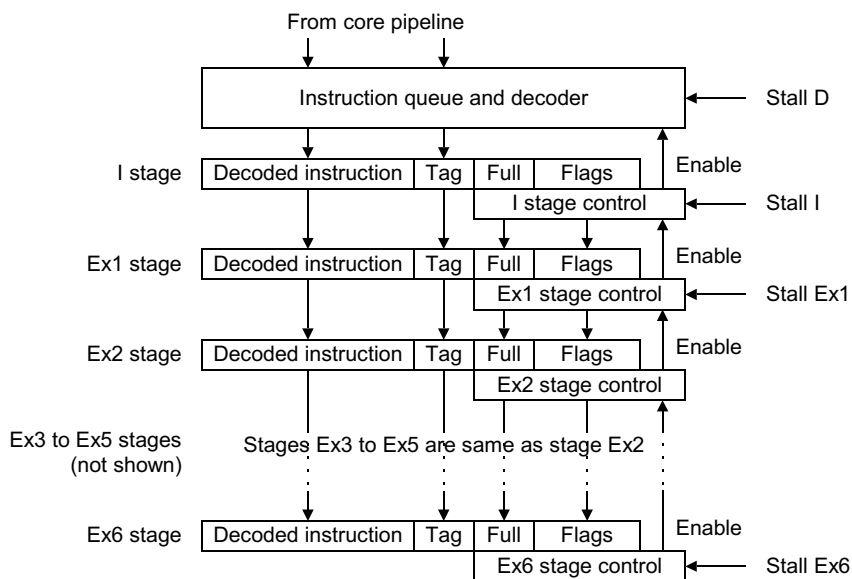

The coprocessor pipeline is very similar to the core pipeline, but lacks the fetch stages. Instructions are passed from the core directly into the Decode stage of the coprocessor pipeline, which takes the form of a FIFO queue.

The Decode stage then decodes the instruction, rejecting non-coprocessor instructions and any coprocessor instructions containing a nonmatching coprocessor number.

The length of any vectored data transfer is also decided at this point and sent back to the core. The decoded instruction then passes into the issue (I) stage. This stage decides if this particular instance of the instruction can be accepted. If it cannot, because it addresses a non-existent register, the instruction is bounced, informing the core that it cannot be accepted.

If the instruction is both valid and executable, it then passes down the execution pipeline, Ex1 to Ex6. At the bottom of the pipeline, in Ex6, the instruction waits for retirement, which it can do when it receives a matching token from another queue fed by the core.

Figure 11-3 shows the coprocessor pipeline, the main fields within each stage, and the main control signals. Each stage controls the flow of information from the previous stage in the pipeline by passing its Enable signal back. When a pipeline stage is not enabled, it cannot accept information from the previous stage.

**Figure 11-3 Coprocessor pipeline**

Each pipeline stage contains a decoded instruction, and a tag, plus a few status flags:

- Full flag** This flag is set whenever the pipeline stage contains an instruction.
- Dead flag** This flag is set to indicate that the instruction in the stage is a phantom. See *Cancel operations* on page 11-23.
- Tail flag** This flag is set to indicate that the instruction is the tail of an iterated instruction. See *Loads* on page 11-19.

There might also be other flags associated with the decoding of the instruction.

Each stage is controlled not only by its own state, but also by external signals and signals from the following stage, as follows:

- Stall** This signal prevents the stage from accepting a new instruction or passing its own instruction on, and only affects the D, I, Ex1, and Ex6 stages.
- Iterate** This signal indicates that the instruction in the stage must be iterated to implement a multiple load/store and only applies to the I stage.
- Enable** This signal indicates that the next stage in the pipeline is ready to accept data from the current stage.

These signals are combined with the current state of the pipeline to determine if the stage can accept new data, and what the new state of the stage is going to be. Table 11-3 shows how the new state of the pipeline stage is derived.

**Table 11-3 Pipeline stage update**

| Stall | Enable input | Iterate | State | Enable | To next stage | Remarks                           |
|-------|--------------|---------|-------|--------|---------------|-----------------------------------|
| 0     | 0            | X       | Empty | 1      | None          | Bubble closing                    |
| 0     | 0            | X       | Full  | 0      | -             | Stalled by next stage             |
| 0     | 1            | 0       | Empty | 1      | None          | Normal pipeline movement          |
| 0     | 1            | 0       | Full  | 1      | Current       | Normal pipeline movement          |
| 0     | 1            | 1       | Empty | -      | -             | Impossible                        |
| 0     | 1            | 1       | Full  | 0      | Current       | Iteration (I stage only)          |
| 1     | X            | X       | X     | 0      | None          | Stalled (D, I, Ex1, and Ex6 only) |

The Enable input comes from the next stage in the pipeline and indicates if data can be passed on. In general, if this signal is unasserted then the pipeline stage cannot receive new data or pass on its own contents. However, if the pipeline stage is empty it can

receive new data without passing any data on to the next stage. This is known as *bubble closing*, because it has the effect of filling up empty stages in the pipeline by enabling them to move on while lower stages are stalled.

### 11.2.5 Instruction tagging

It is sometimes necessary for the core to be able to identify instructions in the coprocessor pipeline. This is necessary for flushing (see *Flush operations* on page 11-24) so that the core can indicate to the coprocessor which instructions are to be flushed. The core therefore gives each instruction sent to the coprocessor a tag, which is drawn from a pool of values large enough so that all the tags in the pipeline at any moment are unique. Sixteen tags are sufficient to achieve this, requiring a four-bit tag field. Each time a tag is assigned to an instruction, the tag number is incremented modulo 16 to generate the next tag.

The flushing mechanism is simplified because successive coprocessor instructions have contiguous tags. The core manages this by only incrementing the tag number when the instruction passed to the coprocessor is a coprocessor instruction. This is done after sending the instruction, so the tag changes after a coprocessor instruction is sent, rather than before. It is not possible to increment the tag before sending the instruction because the core has not yet had time to decode the instruction to determine what kind of instruction it is. When the coprocessor Decode stage removes the non-coprocessor instructions, it is left with an instruction stream carrying contiguous tags.

The tags can also be used to verify that the sequence of tokens moving down the queues matches the sequence of instructions moving down the core and coprocessor pipelines.

### 11.2.6 Flush broadcast

If a branch has been mispredicted, it might be necessary for the core to flush both pipelines. Because this action potentially affects the entire pipeline, it is not passed across in a queue but is broadcast from the core to the coprocessor, subject to the same timing constraints as the queues. When the flush signal is received by the coprocessor, it causes the pipeline and the instruction queue to be cleared up to the instruction triggering the flush. This is explained in more detail in *Flush operations* on page 11-24.

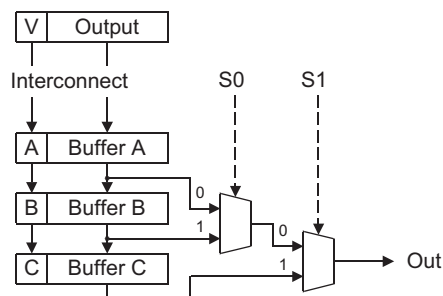

## 11.3 Token queue management

The token queues, all of which are three slots long and function identically, are implemented as short FIFOs. An example implementation of the queues is described in:

- *Queue implementation*
- *Queue modification*
- *Queue flushing* on page 11-12.

### 11.3.1 Queue implementation

The queue FIFOs are implemented as three registers, with the current output selected by using multiplexors. Figure 11-4 shows this arrangement.

**Figure 11-4 Token queue buffers**

The queue consists of three registers, each of which is associated with a flag that indicates if the register contains valid data. New data are moved into the queue by being written into buffer A and continue to move along the queue if the next register is empty, or is about to become empty. If the queue is full, the oldest data, and therefore the first to be read from the queue, occupies buffer C and the newest occupies buffer A.

The multiplexors also select the current flag, which then indicates if the selected output is valid.

### 11.3.2 Queue modification

The queue is written to on each cycle. Buffer A accepts the data arriving at the interface, and the buffer A flag accepts the valid bit associated with the data. If the queue is not full, this results in no loss of data because the contents of buffer A are moved to buffer B during the same cycle.

If the queue is full, then the loading of buffer A is inhibited to prevent loss of data. In any case, no valid data is presented by the interface when the queue is full, so no data loss ensues.

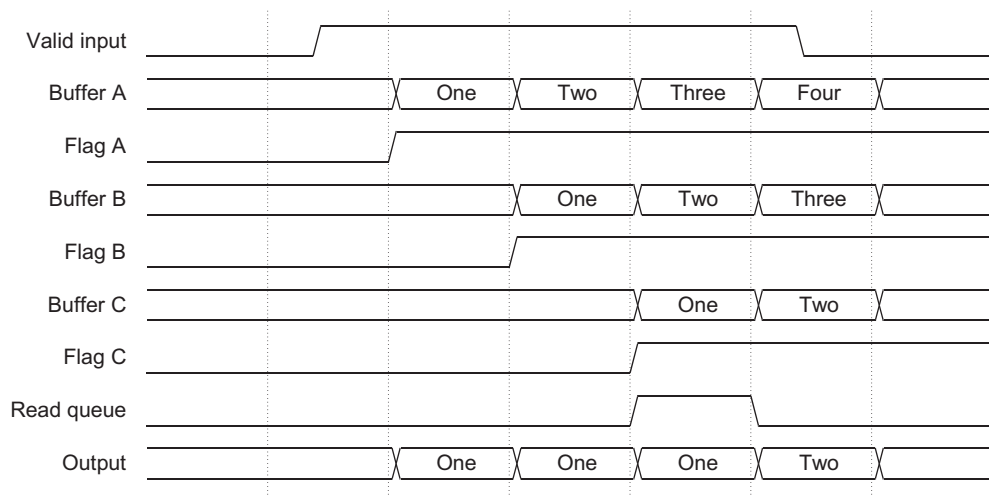

The state of the three buffer flags is used to decide which buffer provides the queue output during each cycle. The output is always provided by the buffer containing the oldest data. This is buffer C if it is full, or buffer B or, if that is empty, buffer A.

A simple priority encoder, looking at the three flags, can supply the correct multiplexor select signals. The state of the three flags can also determine how data are moved from one buffer to another in the queue. Table 11-4 shows how the three flags are decoded.

**Table 11-4 Addressing of queue buffers**

| Flag C | Flag B | Flag A | S1 | S0 | Remarks                        |
|--------|--------|--------|----|----|--------------------------------|
| 0      | 0      | 0      | X  | X  | Queue is empty                 |
| 0      | 0      | 1      | 0  | 0  | B = A                          |
| 0      | 1      | 0      | 0  | 1  | C = B                          |
| 0      | 1      | 1      | 0  | 1  | C = B, B = A                   |
| 1      | 0      | 0      | 1  | X  | -                              |
| 1      | 0      | 1      | 1  | X  | B = A                          |
| 1      | 1      | 0      | 1  | X  | -                              |
| 1      | 1      | 1      | 1  | X  | Queue is full. Input inhibited |

New data can be moved into buffer A, provided the queue is not full, even if its flag is set, because the current contents of buffer A are moved to buffer B. When the queue is read, the flag associated with the buffer providing the information must be cleared. This operation can be combined with an input operation so that the buffer is overwritten at the end of the cycle during which it provides the queue output. This can be implemented by using the read enable signal to mask the flag of the selected stage, making it available for input. Figure 11-5 on page 11-12 shows reading and writing a queue.

**Figure 11-5 Queue reading and writing**

Four valid inputs (labeled One, Two, Three, and Four) are written into the queue, and are clocked into buffer A as they arrive. Figure 11-5 shows how these inputs are clocked from buffer to buffer until the first input reaches buffer C. At this point a read from the queue is required. Because buffer C is full, it is chosen to supply the data. Because it is being read, it is free to accept more input, and so it receives the value Two from buffer B, which in turn receives the value Three from buffer A. Because buffer A is being emptied by writing to buffer B, it can accept the value Four from the input.

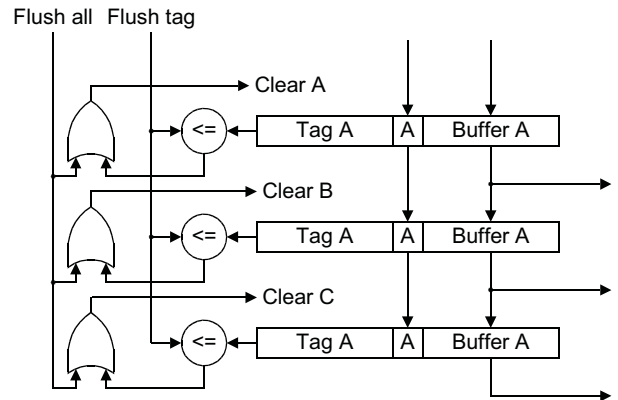

### 11.3.3 Queue flushing

When the coprocessor pipeline is flushed, in response to a command from the core, some of the queues might also require flushing. There are two possible ways of flushing the queue:

- the entire queue is cleared
- the queue is flushed from a selected buffer, along with all data in the queue newer than the data in the selected buffer.

The method used depends on the point at which flushing begins in the coprocessor pipeline. See *Flush operations* on page 11-24 for more details. A flush command has associated with it a tag value that indicates where the queue flushing starts. This is matched with the tag carried by every instruction.

If the queue is to be flushed from a selected buffer, the buffer is chosen by looking for a matching tag. When this is found, the flag associated with that buffer is cleared, and every flag newer than the selected one is also cleared. Figure 11-6 shows queue flushing.

**Figure 11-6 Queue flushing**

Each buffer in the queue has a tag comparator associated with it. The flush tag is presented to each comparator, to be compared with the tag belonging to each valid instruction held in the queue. The flush tag is compared with each tag in the queue. If the flush tag is the same as, or older than, any tag then that queue entry has its Full flag cleared. This indicates that it is empty. A less-than-or-equal-to comparison is used to identify tags that are to be flushed. If a tag in the pipeline later than the queue matches, the Flush all signal is asserted to clear the entire queue.

## 11.4 Token queues

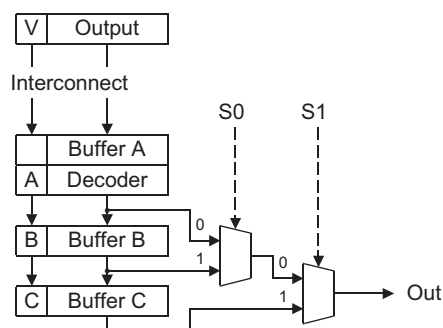

Each of the synchronizing queues is described in the following sections:

- *Instruction queue*
- *Length queue* on page 11-15
- *Accept queue* on page 11-16
- *Cancel queue* on page 11-16
- *Finish queue* on page 11-17.

### 11.4.1 Instruction queue

The core passes every instruction fetched from memory across the coprocessor interface, where it enters the instruction queue. Ideally it only passes on the coprocessor instructions, but has not, at this stage, had time to decode the instruction.

The coprocessor decodes the instruction on arrival in its own Decode stage and rejects the non-coprocessor instructions. The core does not require any acknowledgement of the removal of these instructions because each instruction type is determined within the coprocessors Decode stage. This means that the instruction received from the core must be decoded as soon as it enters the instruction queue. The instruction queue is a modified version of the standard queue, which incorporates an instruction decoder. Figure 11-7 shows an instruction queue implementation.

**Figure 11-7 Instruction queue**

The decoder decodes the instruction written into buffer A as soon as it arrives. The subsequent buffers, B and C, receive the decoded version of the instruction in buffer A.

The A flag now indicates that the data in buffer A are valid and represent a coprocessor instruction. This means that non-coprocessor or unrecognized instructions are immediately dropped from the instruction queue and are never passed on.

The coprocessor must also compare the coprocessor number field in a coprocessor instruction and compare it with its own number, given by **ACPNUM**. If the number does not match, the instruction is invalid. The instruction queue provides an interface to the core through the following signals, which are all driven by the core:

- ACPINSTRV** This signal is asserted when valid data are available from the core. It must be clocked directly into the buffer A flag, unless the queue is full, in which case it is ignored.
- ACPINSTR[31:0]** This is the instruction being passed to the coprocessor from the core, and must be clocked into buffer A.
- ACPINSTRT[3:0]** This is the flush tag associated with the instruction in **ACPINSTR**, and must be clocked into the tag associated with buffer A.

The instruction queue feeds the issue stage of the coprocessor pipeline, providing a new input to the pipeline, in the form of a decoded instruction and its associated tag, whenever the queue is not empty.

### 11.4.2 Length queue

When a coprocessor has decoded an instruction it knows how long a vectored load/store operation is. This information is sent with the synchronizing token down the length queue, as the relevant instruction leaves the instruction queue to enter the issue stage of the pipeline. The length queue is maintained by the core and the coprocessor communicates with the queue using the following signals:

#### **CPALENGTH[3:0]**

This is the length of a vectored data transfer to or from the coprocessor. It is determined by the decoder in the instruction queue and asserted as the decoded instruction moves into the issue stage. If the current instruction does not represent a vectored data transfer, the length value is set to zero.

#### **CPALENGTHT[3:0]**

This is the tag associated with the instruction leaving the instruction queue, and is copied from the queue buffer supplying the instruction.

#### **CPALENGTHHOLD**

This is deasserted when the instruction queue is providing valid information to the core length queue. Otherwise, the signal is asserted to indicate that no valid data are available.

### 11.4.3 Accept queue

The coprocessor must decide in the issue stage if it can accept an otherwise valid coprocessor instruction. It passes this information with the synchronizing token down the accept queue, as the relevant instruction passes from the issue stage to Ex1.

If an instruction cannot be accepted by the coprocessor it is said to have been bounced. If the coprocessor bounces an instruction it does not remove the instruction from its pipeline, but converts it to a phantom. This is explained in more detail in *Bounce operations* on page 11-23.

The accept queue is maintained by the core and the coprocessor communicates with the queue using the following signals, which are all driven by the coprocessor:

#### **CPAACCEPT**

This is set to indicate that the instruction leaving the coprocessor issue stage has been accepted.

#### **CPAACCEPTT[3:0]**

This is the tag associated with the instruction leaving the issue stage.

#### **CPAACCEPTHOLD**

This is deasserted when the issue stage is passing an instruction on to the Ex1 stage, whether it has been accepted or not. Otherwise, the signal is asserted to indicate that no valid data are available.

#### ———— **Note** ————

If no coprocessor is connected, the following signals must be driven LOW.

- **CPALENGTHHOLD**
- **CPAACCEPT**
- **CPAACCEPTHOLD**

### 11.4.4 Cancel queue

The core might want to cancel an instruction that it has already passed on to the coprocessor. This can happen if the instruction fails its condition codes, which requires the instruction to be removed from the instruction stream in both the core and the coprocessor.

The queue, which is a standard queue as described in *Token queue management* on page 11-10, is maintained by the coprocessor and is read by the coprocessor Ex1 stage.

The cancel queue provides an interface to the core through the following signals, which are all driven by the core:

#### **ACPCANCELV**

This signal is asserted when valid data are available from the core. It must be clocked directly into the buffer A flag, unless the queue is full, in which case it is ignored.

#### **ACPCANCEL**

This is the cancel command being passed to the coprocessor from the core, and must be clocked into buffer A.

#### **ACPCANCEL[3:0]**

This is the flush tag associated with the cancel command, and must be clocked into the tag associated with buffer A.

The cancel queue is read by the coprocessor Ex1 stage, which acts on the value of the queued **ACPCANCEL** signal by removing the instruction from the Ex1 stage if the signal is set, and not passing it on to the Ex2 stage.

### **11.4.5 Finish queue**

The finish queue maintains synchronism at the end of the pipeline by providing permission for CDP instructions in the coprocessor pipeline to retire. The queue, which is a standard queue as described in *Token queue management* on page 11-10, is maintained by the coprocessor and is read by the coprocessor Ex6 stage.

The finish queue provides an interface to the core using the **ACPFINISHV** signal, which is driven by the core.

This signal is asserted to indicate that the instruction in the coprocessor Ex6 stage can retire. It must be clocked directly into the buffer A flag, unless the queue is full, in which case it is ignored.

The finish queue is read by the coprocessor Ex6 stage, which can retire a CDP instruction if the finish queue is not empty.

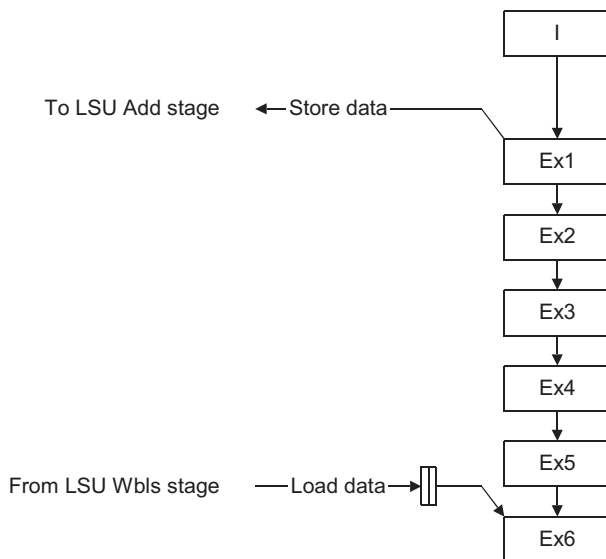

## 11.5 Data transfer

Data transfers are managed by the LSU on the core side, and the pipeline itself on the coprocessor side. Transfers can be a single value or a vector. In the latter case, the coprocessor effectively converts a multiple transfer into a series of single transfers by iterating the instruction in the issue stage. This creates an instance of the load/store instruction for each item to be transferred.

The instruction stays in the coprocessor issue stage while it iterates, creating copies of itself that move down the pipeline. Figure 11-9 on page 11-19 illustrates this process for a load instruction.

The first of the iterated instructions, shown in uppercase, is the head and the others (shown in lowercase) are the tails. In the example shown the vector length is four so there is one head and three tails. At the first iteration of the instruction, the tail flag is set so that subsequent iterations send tail instructions down the pipeline. In the example shown in Figure 11-9 on page 11-19, instruction B has stalled in the Ex1 stage (which might be caused by the cancel queue being empty), so that instruction C does not iterate during its first cycle in the issue stage, but only starts to iterate after the stall has been removed.

Figure 11-8 shows the extra paths required for passing data to and from the coprocessor.

**Figure 11-8 Coprocessor data transfer**

Two data paths are required:

- One passes store data from the coprocessor to the core, and this requires a queue, which is maintained by the core.
- The other passes load data from the core to the coprocessor and requires no queue, only two pipeline registers.

Figure 11-9 shows instruction iteration for loads.

| I    | A | B | [C] | C | c | c | c | D |   |    |    |    |    |    |  |
|------|---|---|-----|---|---|---|---|---|---|----|----|----|----|----|--|
| Ex1  |   | A | [B] | B | C | c | c | c | D |    |    |    |    |    |  |
| Ex2  |   |   | A   |   | B | C | c | c | c | D  |    |    |    |    |  |
| Ex3  |   |   |     | A |   | B | C | c | c | c  | D  |    |    |    |  |
| Ex4  |   |   |     |   | A |   | B | C | c | c  | c  | D  |    |    |  |
| Ex5  |   |   |     |   |   | A |   | B | C | c  | c  | c  | D  |    |  |
| Ex6  |   |   |     |   |   |   | A |   | B | C  | c  | c  | c  | D  |  |
| Time | 1 | 2 | 3   | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 |  |

**Figure 11-9 Instruction iteration for loads**

Only the head instruction is involved in token exchange with the core pipeline, which does not iterate instructions in this way, the tail instructions passing down the pipeline silently.

When an iterated load/store instruction is cancelled or flushed, all the tail instructions (bearing the same tag) must be removed from the pipeline. Only the head instruction becomes a phantom when cancelled. Any tail instruction can be left intact in the pipeline because it has no other effect.

Because the cancel token is received in the coprocessor Ex1 stage, a cancelled iterated instruction always consists of a head instruction in Ex1 and a single tail instruction in the issue stage.

### 11.5.1 Loads

Load data emerge from the WBIs stage of the core LSU and are received by the coprocessor Ex6 stage. Each item in a vectored load is picked up by one instance of the iterated load instruction.

The pipeline timing is such that a load instruction is always ready, or has arrived, in Ex6 to pick up each data item. If a load instruction has arrived in Ex6, but the load information has not yet appeared, the load instruction must stall in Ex6, stalling the rest of the coprocessor pipeline.

The following signals are driven by the core to pass load data across to the coprocessor:

### ACPLDVALID

This signal, when set, indicates that the associated data are valid.

### ACPLDDATA[63:0]

This is the information passed from the core to the coprocessor.

### Load buffers

To achieve correct alignment of the load data with the load instruction in the coprocessor Ex6 stage, the data must be double buffered when they arrive at the coprocessor. Figure 11-10 shows an example.

**Figure 11-10 Load data buffering**

The load data buffers function as pipeline registers and so require no flow control and do not have to carry any tags. Only the data and a valid bit are required. For load transfers to work:

- instructions must always arrive in the coprocessor Ex6 stage coincident with, or before, the arrival of the corresponding instruction in the core WBIs stage
- finish tokens from the core must arrive at the same time as the corresponding load data items arrive at the end of the load data pipeline buffers
- the LSU must see the token from the accept queue before it enables a load instruction to move on from its Add stage.

### Loads and flushes

If a flush does not involve the core WBIs stage it cannot affect the load data buffers, and the load transfer completes normally. If a flush is initiated by an instruction in the core WBIs stage, this is not a load instruction because load instructions cannot trigger a flush. Any coprocessor load instructions behind the flush point find themselves stalled if they get as far as the Ex6 stage, for the lack of a finish token, so no data transfers can have taken place. Any data in the load data buffers expires naturally during the flush dead period while the pipeline reloads.

### Loads and cancels

If a load instruction is canceled both the head and any tails must be removed. Because the cancellation happens in the coprocessor Ex1 stage, no data transfers can have taken place and therefore no special measures are required to deal with load data.

### Loads and retirement

When a load instruction reaches the bottom of the coprocessor pipeline it must find a data item at the end of the load data buffer. This applies to both head and tail instructions. Load instructions do not use finish queue.

## 11.5.2 Stores

Store data emerge from the coprocessor issue stage and are received by the core LSU DC1 stage. Each item of a vectored store is generated because the store instruction iterates in the coprocessor issue stage. The iterated store instructions then pass down the pipeline but have no more use, except to act as place markers for flushes and cancels.

The following signals control the transfer of store data across the coprocessor interface:

#### **CPASTDATAV**

This signal is asserted when valid data is available from the coprocessor.

#### **CPASTDATAT[3:0]**

This is the tag associated with the data being passed to the core.

#### **CPASTDATA[63:0]**

This is the information passed from the coprocessor to the core.

## ACPSTSTOP

This signal from the core prevents additional transfers from the coprocessor to the core, and is raised when the store queue, maintained by the core, can no longer accept any more data. When the signal is deasserted, data transfers can resume.

When **ACPSTSTOP** is asserted, the data previously placed onto **CPASTDATA** must be left there, until new data can be transferred. This enables the core to leave data on **CPASTDATA** until there is sufficient space in the store data queue.

## Store data queue

Because the store data transfer can be stopped at any time by the LSU, a store data queue is required. Additionally, because store data vectors can be of arbitrary length, flow control is required. A queue length of three slots is sufficient to enable flow control to be used without loss of data.

## Stores and flushes

When a store instruction is involved in a flush, the store data queue must be flushed by the core. Because the queue continues to fill for two cycles after the core notifies the coprocessor of the flush (because of the signal propagation delay) the core must delay for two cycles before carrying out the store data queue flush. The dead period after the flush extends sufficiently far to enable this to be done.

## Stores and cancels

If the core cancels a store instruction, the coprocessor must ensure that it sends no store data for that instruction. It can achieve this by either:

- delaying the start of the store data until the corresponding cancel token has been received in the Ex1 stage
- looking ahead into the cancel queue and start the store data transfer when the correct token is seen.

## Stores and retirement

Because store instructions do not use the finish token queue they are retired as soon as they leave the Ex1 stage of the pipeline.

## 11.6 Operations

This section describes the various operations that can be performed and events that can take place.

### 11.6.1 Normal operation

In normal operation the core passes all instructions across to the coprocessor, and then increments the tag if the instruction was a coprocessor instruction. The coprocessor decodes the instruction and throws it away if it is not a coprocessor instruction or if it contains the wrong coprocessor number.

Each coprocessor instruction then passes down the pipeline, sending a token down the length queue as it moves into the issue stage. The instruction then moves into the Ex1 stage, sending a token down the accept queue, and remains there until it has received a token from the cancel queue.

If the cancel token does not request that the instruction is cancelled, and is not a Store instruction, it moves on to the Ex2 stage. The instruction then moves down the pipeline until it reaches the Ex6 stage. At this point it waits to receive a token from the finish queue, which enables it to retire, unless it is either:

- a store instruction, in which case it requires no token from the finish queue
- a load instruction, in which case it must wait until load data are available.

Store instructions are removed from the pipeline as soon as they leave the Ex1 stage.

Instructions with opcode[27:24] as b1100, b1101 or b1110 and where opcode[11:8] match the coprocessors number are treated as coprocessor instructions.

Non-coprocessors instructions can be ignored, but coprocessor instructions must either be executed or bounced.

### 11.6.2 Cancel operations

When the coprocessor instruction reaches the Ex1 stage it looks for a token in the cancel queue. If the token indicates that the instruction is to be cancelled, it is removed from the pipeline and does not pass to Ex2. Any tail instruction in the I stage is also removed.

### 11.6.3 Bounce operations

The coprocessor can reject an instruction by bouncing it when it reaches the issue stage. This can happen to an instruction that has been accepted as a valid coprocessor instruction by the decoder, but that is found to be unexecutable by the issue stage, perhaps because it refers to a non-existent register or operation.

When the bounced instruction leaves the issue stage to move into Ex1, the token sent down the accept queue has its bounce bit set. This causes the instruction to be removed from the core pipeline.

When the instruction moves into Ex1 it has its dead bit set, turning it into a phantom. This enables the instruction to remain in the pipeline to match tokens in the cancel queue.

The core posts a token for the bounced instruction before the coprocessor can bounce it, so the phantom is required to pick up the token for the bounced instruction. The instruction is otherwise inert, and has no other effect.

The core might already have decided to cancel the instruction being bounced. In this case, the cancel token causes the phantom to be removed from the pipeline. If the core does not cancel the phantom it continues to the bottom of the pipeline.

Any instruction that is identified as a coprocessor instruction must be bounced if the coprocessor cannot execute it. This includes instructions in the coprocessor extension space, where opcode[27:21] is set to b1100000, which must always be bounced.

#### 11.6.4 Flush operations

A flush can be triggered by the core in any stage from issue to WBIs inclusive. When this happens a broadcast signal is received by the coprocessor, passing it the tag associated with the instruction triggering the flush.

Because the tag is changed by the core after each new coprocessor instruction, the tag matches the first coprocessor instruction following the instruction causing the flush. The coprocessor must then find the first instruction that has a matching tag, working from the bottom of the pipeline upwards, and remove all instructions from that point upwards.

Unlike tokens passing down a queue, a flush signal has a fixed delay so that the timing relationship between a flush in the core and a flush in the coprocessor is known precisely.

Most of the token queues also require flushing and this can also be done using the tags attached to each instruction. If a match has been found before the stage at the receiving end of a token queue is passed, then the token queue is cleared.

Otherwise, it must be properly flushed by matching the tags in the queue. This operation must be performed on all the queues except the finish queue, which is updated in the normal way. Therefore, the coprocessor must flush the instruction and cancel queues.

The flushing operation can be carried out by the coprocessor as soon as the flush signal is received. The flushing operation is simplified because the instruction and cancel queues cannot be performing any other operation. This means that flushing does not have to be combined with queue updates for these queues.

There is a single cycle following a flush in which nothing happens that affects the flushed queues, and this provides a good opportunity to carry out the queue flushing operation.

The following signals provide the flush broadcast signal from the core:

**ACPFLUSH** This signal is asserted when a flush is to be performed.

**ACPFLUSHT[3:0]**

This is the tag associated with the first instruction to be flushed.

### 11.6.5 Retirement operations

When an instruction reaches the bottom of the coprocessor pipeline it is retired. How it retires depends on the kind of instruction it is and if it is iterated, as shown in Table 11-5.

**Table 11-5 Retirement conditions**

| Instruction | Type  | Retirement conditions                                                         |
|-------------|-------|-------------------------------------------------------------------------------|
| CDP         | -     | Must find a token in the finish queue.                                        |
| MRC         | Store | No conditions. Immediate retirement on leaving Ex1.                           |
| MCR         | Load  | All load instructions must find data in the load data pipeline from the core. |
| MRRC        | Store | No conditions. Immediate retirement on leaving Ex1.                           |
| MCRR        | Load  | All load instructions must find data in the load data pipeline from the core. |
| STC         | Store | No conditions. Immediate retirement on leaving Ex1.                           |
| LDC         | Load  | Must find data in the load data pipeline from the core.                       |

Table 11-5 lists the conditions for each coprocessor instruction:

- all store instructions retire unconditionally on leaving Ex1 because no token is required in the finish queue
- CDP instructions require a token in the finish queue
- all load instructions must pick up data from the load pipeline
- phantom load instructions retire unconditionally.

## 11.7 Multiple coprocessors

There might be more than one coprocessor attached to the core, and so some means is required for dealing with multiple coprocessors. It is important, for reasons of economy, to ensure that as little of the coprocessor interface is duplicated. In particular, the coprocessors must share the length, accept, and store data queues, which are maintained by the core.

If these queues are to be shared, only one coprocessor can use the queues at any time. This is achieved by enabling only one coprocessor to be active at any time. This is not a serious limitation because only one coprocessor is in use at any time.

Typically, a processor is driven through driver software, which drives one coprocessor. Calls to the driver software, and returns from it, ensure that there are several core instructions between the use of one coprocessor and the use of a different coprocessor.

### 11.7.1 Interconnect considerations

If only one coprocessor is permitted to communicate with the core at any time, all coprocessors can share the coprocessor interface signals from the core. Signals from the coprocessors to the core can be ORed together, provided that every coprocessor holds its outputs to zero when it is inactive.

### 11.7.2 Coprocessor selection

Coprocessors are enabled by a signal **ACPENABLE** from the core. There are 12 of these signals, one for each coprocessor. Only one can be active at any time. In addition, instructions to the coprocessor include the coprocessor number, enabling coprocessors to reject instructions that do not match their own number. Core instructions are also rejected.

### 11.7.3 Coprocessor switching

When the core decodes a coprocessor instruction destined for a different coprocessor to that last addressed, it stalls this instruction until the previous coprocessor instruction has been retired. This ensures that all activity in the currently selected coprocessor has ceased.

The coprocessor selection is switched, disabling the last active coprocessor and activating the new coprocessor. The disabled coprocessor ignores the new coprocessor instruction. Therefore, the instruction is resent by the core, and is now accepted by the newly activated coprocessor.

A coprocessor is disabled by the core by setting **ACPENABLE** LOW for the selected coprocessor. The coprocessor responds by ceasing all activity and setting all its output signals LOW.

When the coprocessor is enabled, which is signaled by setting **ACPENABLE** HIGH, it must immediately set the signals **CPALENGTHHOLD** and **CPAACCEPTHOLD** HIGH, and **CPASTDATAV** LOW, because the pipeline is empty at this point. The coprocessor can then start normal operation.

# Chapter 12

## Vectored Interrupt Controller Port

This chapter describes the ARM1156T2F-S Vectored Interrupt Controller port. It contains the following sections:

- *About the PL192 Vectored Interrupt Controller* on page 12-2
- *About the ARM1156T2F-S VIC port* on page 12-3
- *Timing of the VIC port* on page 12-6
- *Interrupt entry flowchart* on page 12-9.

## 12.1 About the PL192 Vectored Interrupt Controller

An interrupt controller is a peripheral that is used to handle multiple interrupt sources. Features usually found in an interrupt controller are:

- multiple interrupt request inputs, one for each interrupt source, and one interrupt request output for the processors interrupt request input
- software can mask out particular interrupt requests
- prioritization of interrupt sources for interrupt nesting.

In a system with an interrupt controller having the above features, software is still required to:

- determine which interrupt source is requesting service
- determine where the service routine for that interrupt source is loaded.

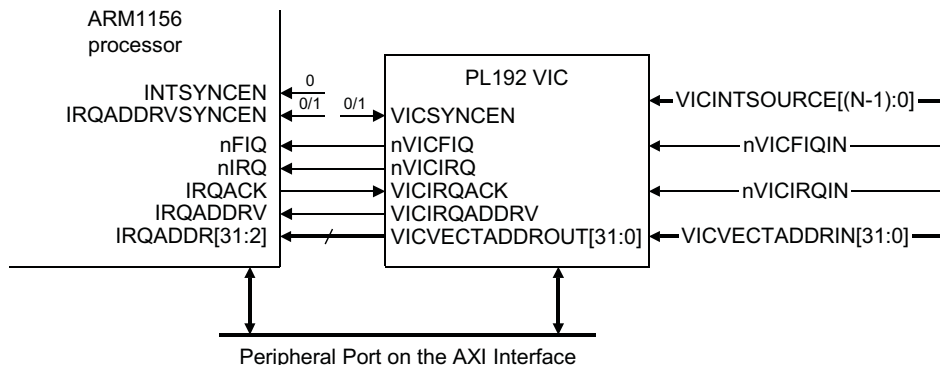

A *Vectored Interrupt Controller* (VIC) does both things in hardware. It supplies the starting address (vector address) of the service routine corresponding to the highest priority requesting interrupt source.

The PL192 VIC is an *Advanced Microcontroller Bus Architecture* (AMBA) compliant, *System-on-Chip* (SoC) peripheral that is developed, tested, and licensed by ARM Limited for use in ARM1156T2F-S designs.

The ARM1156T2F-S VIC port and the Peripheral Interface enable you to connect a PL192 VIC to an ARM1156T2F-S processor. For more details the *ARM PrimeCell Vectored Interrupt Controller (PL192) Technical Reference Manual*.

## 12.2 About the ARM1156T2F-S VIC port

Figure 12-1 shows the VIC port and the Peripheral Interface connecting a PL192 VIC and an ARM1156T2F-S processor.

**Figure 12-1 Connection of a PL192 VIC to an ARM1156T2F-S processor**

The VIC port enables the processor to read the vector address as part of the IRQ interrupt entry. The ARM1156T2F-S processor takes a vector address from this interface instead of using the pre-ARMv6 addresses, that is 0x00000018 or 0xFFFF0018.

The VIC port does not support the reading of FIQ vector addresses.

The interrupt interface is capable of managing interrupts asserted by a controller that clocks synchronously to the ARM1156T2F-S processor clock. This ensures that the controller is used in systems that have a synchronous interface between the core clock and the AMBA clock.

The VIC port consists of the signals shown in Table 12-1.

**Table 12-1 VIC port signals**

| Signal name           | Direction | Description                                                                                      |
|-----------------------|-----------|--------------------------------------------------------------------------------------------------|
| <b>nFIQ</b>           | Input     | Active LOW fast interrupt request signal.                                                        |
| <b>nIRQ</b>           | Input     | Active LOW normal interrupt request signal.                                                      |
| <b>INTSYNCEN</b>      | Input     | If this signal is asserted, the internal <b>nFIQ</b> and <b>nIRQ</b> synchronizers are bypassed. |
| <b>IRQADDRVSYNCEN</b> | Input     | If this signal is asserted, the internal <b>IRQADDRV</b> synchronizer is bypassed.               |

Table 12-1 VIC port signals (continued)

| Signal name          | Direction | Description                                                                                                                    |
|----------------------|-----------|--------------------------------------------------------------------------------------------------------------------------------|
| <b>IRQACK</b>        | Output    | Active HIGH IRQ acknowledge.                                                                                                   |
| <b>IRQADDRV</b>      | Input     | Active HIGH valid signal for the IRQ interrupt vector address. Indicates when IRQADDR is valid                                 |
| <b>IRQADDR[31:2]</b> | Input     | IRQ interrupt vector address. <b>IRQADDR[31:2]</b> holds the address of the first ARM or Thumb instruction in the IRQ handler. |

**IRQACK** is driven by the ARM1156T2F-S processor to indicate to an external VIC that the processor wants to read the **IRQADDR** input.

**IRQADDRV** is driven by a VIC to tell the ARM1156T2F-S processor that the address on the **IRQADDR** bus is valid and being held, and so it is safe for the processor to sample it.

**IRQACK** and **IRQADDRV** together implement a four-phase handshake between the ARM1156T2F-S processor and a VIC. See *Timing of the VIC port* on page 12-6 for more details.

## 12.2.1 Synchronization of the VIC port signals

The peripheral port clock enable signal **ACLKENP** can run at any frequency, synchronously to the ARM1156T2F-S processor clock signal.

**nFIQ** and **nIRQ** can be connected to either synchronous or asynchronous sources. Synchronizers are provided internally for the case of asynchronous sources. Pin **INTSYNCEN** is also provided to enable SoC designers to bypass the synchronizers if required. Similarly, a synchronizer is provided inside the ARM1156T2F-S processor for the **IRQADDRV** signal. If this signal is known to be synchronous, the synchronizer can be bypassed by pulling **IRQADDRVSYNCEN** HIGH.

These signals enable SoC designers to reduce interrupt latency if it is known that the **nFIQ**, **nIRQ**, or **IRQADDRV** inputs are always driven by a synchronous source.

When connecting the PL192 VIC to the ARM1156T2F-S processor, **INTSYNCEN** must be tied LOW regardless of the Peripheral Port clocking mode. This is because the PL192 **nVICIRQ** and **nVICFIQ** outputs are completely asynchronous, because there are combinational paths that cross this device through to these outputs. However, **IRQADDRVSYNCEN** must be set depending on the clocking mode.

### **12.2.2 Interrupt handler exit**

The software acknowledges an IRQ interrupt handler exit to a VIC by issuing a write to the vector address register.

## 12.3 Timing of the VIC port

Figure 12-2 shows a timing example of VIC port operation. In this example IRQC is received followed by IRQB having a higher priority. The waveforms in Figure 12-2 shows the relationship between **CLKIN** and the VIC clock, and the delays marked Sync provide what is required for the delay of the synchronizers. When this interface is used synchronously, these delays are reduced to being a single cycle of the receiving clock.

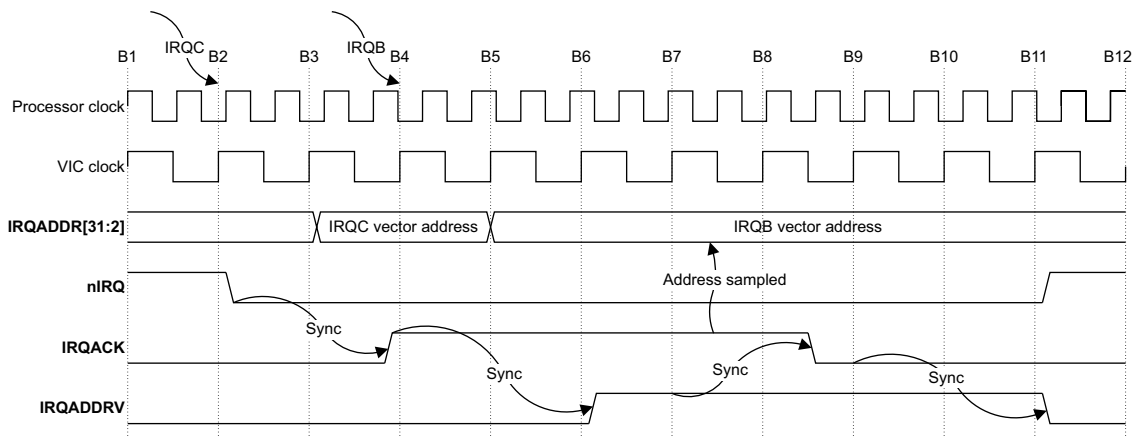

Figure 12-2 VIC port timing example

Figure 12-2 illustrates the basic handshake mechanism that operates between an ARM1156T2F-S processor and a PL192 VIC:

1. An IRQC interrupt request occurs causing the PL192 VIC to set the processor **nIRQ** input.
2. The processor samples the **nIRQ** input LOW and initiates an interrupt entry sequence.
3. Another IRQB interrupt request of higher priority than IRQC occurs.
4. Between B3 and B4, the processor decides that the pending interrupt is an IRQ rather than a FIQ and asserts the **IRQACK** signal.
5. At B4 the VIC samples **IRQACK** HIGH and starts generating **IRQADDRV**. The VIC can still change **IRQADDR** to the IRQB vector address while **IRQADDRV** is LOW.
6. At B6 the VIC asserts **IRQADDRV** while **IRQADDR** is set to the IRQB vector address. **IRQADDR** is held until the processor acknowledges it has sampled it, even if a higher priority interrupt is received while the VIC is waiting.

7. Around B8 the processor samples the value of the **IRQADDR** input bus and deasserts **IRQACK**.
8. When the VIC samples **IRQACK** LOW, it stacks the priority of the **IRQB** interrupt and deasserts **IRQADDRV**. It also deasserts **nIRQ** if there are no higher priority interrupts pending.
9. When the processor samples **IRQADDRV** LOW, it knows it can sample the **nIRQ** input again. Therefore, if the VIC requires some time for deasserting **nIRQ**, it must ensure that **IRQADDRV** stays HIGH until **nIRQ** has been deasserted.

The clearing of the interrupt is handled in software by the interrupt handling routine. This enables multiple interrupt sources to share a single interrupt priority. In addition, the interrupt handling routine must communicate to the VIC that the interrupt currently being handled is complete, using the memory-mapped or coprocessor-mapped interface, to enable the interrupt masking to be unwound.

### 12.3.1 PL192 VIC timing

As its part of the handshake mechanism, the PL192 VIC:

1. Synchronizes **IRQACK** on its way in or bypasses the synchronizers if it is in synchronous mode.
2. Asserts **IRQADDRV** when an address is ready at **IRQADDR**, and holds that address until **IRQACK** is sampled LOW, even if higher priority interrupts come along.
3. Stacks the priority that corresponds to the vector address present at **IRQADDR** when it samples the **IRQACK** signal LOW (while **IRQADDRV** is HIGH).
4. Clears **IRQADDRV** so the processor can recognize another interrupt. If **nIRQ** is also to be deasserted at this point because there are no higher priority interrupts pending, it is deasserted before or at the same time as **IRQADDRV** to ensure that the processor does not take the same interrupt again.

### 12.3.2 Core timing

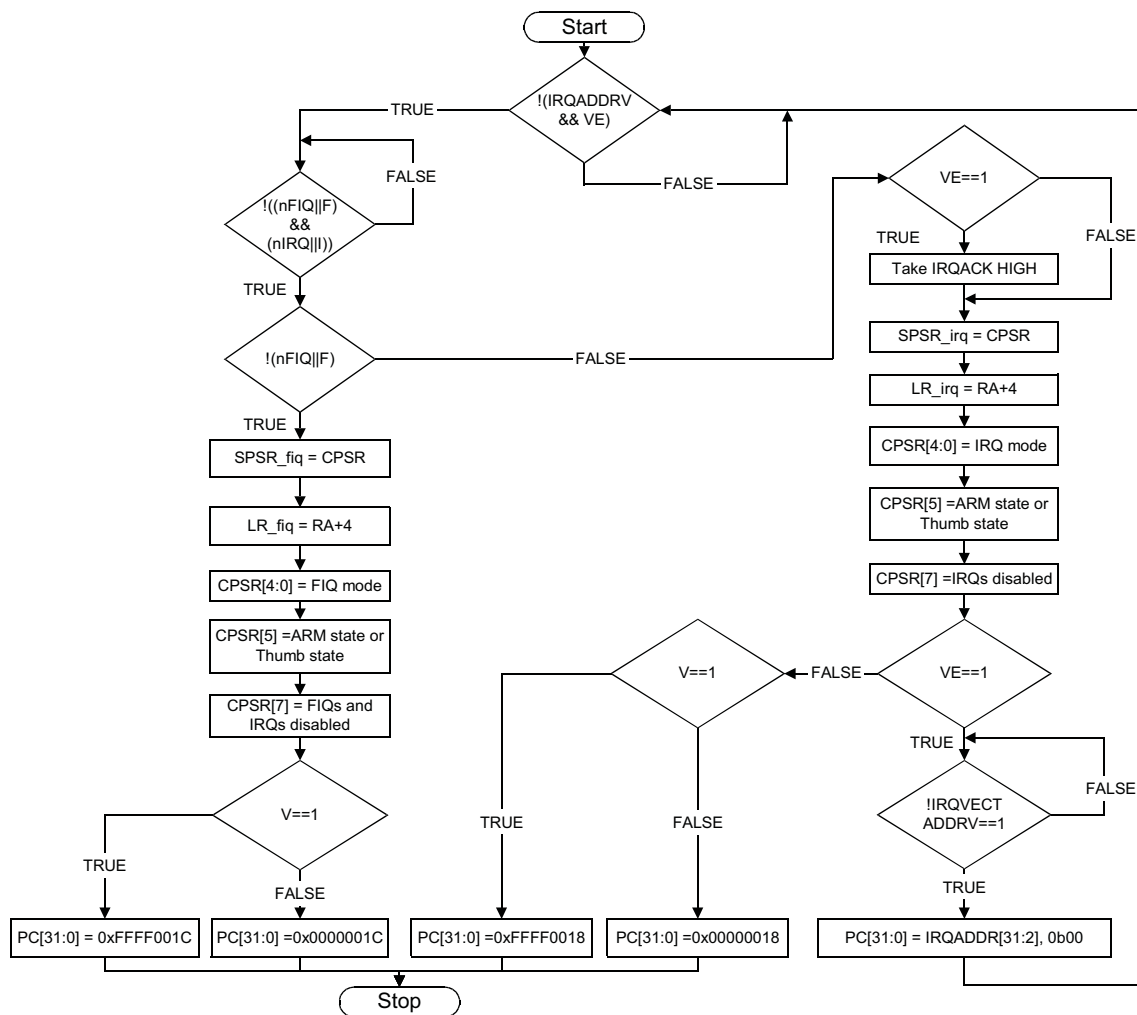

As its part of the handshake mechanism, the core:

1. Starts an interrupt entry sequence when it samples the **nIRQ** signal is LOW.

2. Determines if an FIQ or an IRQ is going to be taken. This happens after the interrupt entry sequence is started. If it decides that an IRQ is going to be taken, it starts the VIC port handshake by asserting **IRQACK**. If it decides that the interrupt is an FIQ, then it does not assert **IRQACK** and the VIC port handshake is not initiated.
3. Ignores the value of the **nFIQ** input until the IRQ interrupt entry sequence is completed if it has decided that the interrupt is an IRQ.
4. Samples the **IRQADDR** input bus when both **IRQACK** and **IRQADDRV** are sampled asserted. The interrupt entry sequence proceeds with this value of **IRQADDR**.
5. Ignores the **nIRQ** signal while **IRQADDRV** is HIGH. This gives the VIC time to deassert the **nIRQ** signal if there is no higher priority interrupt pending.
6. Ignores the **nFIQ** signal while **IRQADDRV** is HIGH.

## 12.4 Interrupt entry flowchart

Figure 12-3 is a flowchart for ARM1156T2F-S interrupt recognition. It shows all the decisions and actions that have to be taken to complete interrupt entry.

**Figure 12-3** Interrupt entry sequence

For details of the I and F bits shown in Figure 12-3, see *The program status registers* on page 2-12. For details of the V, and VE bits shown in Figure 12-3, see *c1, Control Register* on page 3-46.

# Chapter 13

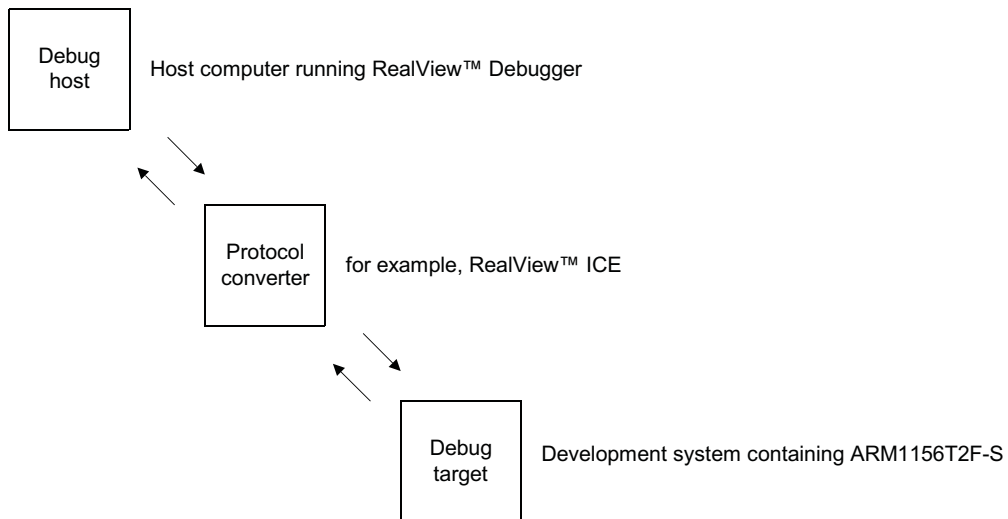

## Debug

This chapter contains details of the ARM1156T2F-S debug unit. These features assist the development of application software, operating systems, and hardware. This chapter contains the following sections:

- *Debug systems* on page 13-2
- *About the debug unit* on page 13-4
- *Debug registers* on page 13-6
- *CP14 registers reset* on page 13-24
- *CP14 debug instructions* on page 13-25
- *Debug events* on page 13-28
- *Debug exception* on page 13-33
- *Debug state* on page 13-35
- *Debug communications channel* on page 13-39
- *Debugging in a cached system* on page 13-40
- *Monitor debug-mode debugging* on page 13-41
- *Halting debug-mode debugging* on page 13-47
- *External signals* on page 13-49.

## 13.1 Debug systems

The ARM1156T2F-S processor forms one component of a debug system that interfaces from the high-level debugging performed by you, to the low-level interface supported by the ARM1156T2F-S processor. A typical system is shown in Figure 13-1.

**Figure 13-1 Typical debug system**

This typical system has three parts:

- *The debug host*
- *The protocol converter*
- *The ARM1156T2F-S processor on page 13-3.*

### 13.1.1 The debug host

The debug host is a computer, for example a personal computer, running a software debugger such as RealView™ Debugger. The debug host enables you to issue high-level commands such as *set breakpoint at location XX*, or *examine the contents of memory from 0x0-0x100*.

### 13.1.2 The protocol converter

The debug host is connected to the ARM1156T2F-S development system using an interface, for example an RS232. The messages broadcast over this connection must be converted to the interface signals of the ARM1156T2F-S processor. This function is performed by a protocol converter, for example, RealView ICE.

### 13.1.3 The ARM1156T2F-S processor

The ARM1156T2F-S processor, with debug unit, is the lowest level of the system. The debug extensions enable you to:

- stall program execution
- examine its internal state and the state of the memory system
- resume program execution.

The debug host and the protocol converter are system-dependent.

## 13.2 About the debug unit

The ARM1156T2F-S debug unit assists in debugging software running on the ARM1156T2F-S processor. You can use an ARM1156T2F-S debug unit, in combination with a software debugger program, to debug:

- application software
- operating systems
- ARM processor based hardware systems.

The debug unit enables you to:

- stop program execution
- examine and alter processor and coprocessor state
- examine and alter memory and input/output peripheral state
- restart the processor core.

you can debug the ARM1156T2F-S processor in the following ways:

- *Halting debug-mode debugging*
- *Monitor debug-mode debugging* on page 13-5
- Trace debugging. See Chapter 15 *Trace Interface Port* for interfacing with an ETM.

The ARM1156T2F-S debug interface is based on the *IEEE Standard Test Access Port and Boundary-Scan Architecture*.

### 13.2.1 Halting debug-mode debugging

When the ARM1156T2F-S debug unit is in Halting debug-mode, the processor halts when a debug event, such as a breakpoint, occurs. When the core is halted, an external host can examine and modify its state using the DBGTAP.

In Halting debug-mode you can examine and alter all processor state (processor registers), coprocessor state, memory, and input/output locations through the DBGTAP. This mode is intentionally invasive to program execution. Halting debug-mode requires:

- external hardware to control the DBGTAP
- a software debugger to provide the user interface to the debug hardware.

See *CP14 c1, Debug Status and Control Register (DSCR)* on page 13-9 to learn how to set the ARM1156T2F-S debug unit into Halting debug-mode.

### 13.2.2 Monitor debug-mode debugging

When the ARM1156T2F-S debug unit is in Monitor debug-mode, the processor takes a Debug exception instead of halting. A special piece of software, a monitor target, can then take control to examine or alter the processor state. Monitor debug-mode is essential in real-time systems where the core cannot be halted to collect information. For example, engine controllers and servo mechanisms in hard drive controllers that cannot stop the code without physically damaging the components.

When debugging in Monitor debug-mode the processor stops execution of the current program and starts execution of a monitor target. The state of the processor is preserved in the same manner as all ARM exceptions (see the *ARM Architecture Reference Manual* on exceptions and exception priorities). The debug monitor target communicates with the debugger to access processor and coprocessor state, and to access memory contents and input/output peripherals. Monitor debug-mode requires a debug monitor program to interface between the debug hardware and the software debugger.

When debugging in Monitor debug-mode, you can program new debug events through CP14. This coprocessor is the software interface of all the debug resources such as the breakpoint and watchpoint registers. See *CP14 c1, Debug Status and Control Register (DSCR)* on page 13-9 to learn how to set the ARM1156T2F-S debug unit into Monitor debug-mode.

### 13.2.3 Programming the debug unit

The ARM1156T2F-S debug unit is programmed using *CoProcessor 14* (CP14). CP14 provides:

- instruction address comparators for triggering breakpoints
- data address comparators for triggering watchpoints
- a bidirectional *Debug Communication Channel* (DCC)
- all other state information associated with ARM1156T2F-S debug.

CP14 is accessed using coprocessor instructions in Monitor debug-mode, and certain debug scan chains in Halting debug-mode, see Chapter 14 *Debug Test Access Port* to learn how to access the ARM1156T2F-S debug unit using scan chains.

### 13.3 Debug registers

Table 13-1 shows definitions of terms used in register descriptions.

Table 13-1 Terms used in register descriptions

| Term                  | Description                                                                                                                                                                                                                                                                                |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R                     | Read-only. Written values are ignored. However, it is written as 0 or preserved by writing the same value previously read from the same fields on the same processor.                                                                                                                      |
| W                     | Write-only. This bit cannot be read. Reads return an Unpredictable value.                                                                                                                                                                                                                  |
| RW                    | Read or write.                                                                                                                                                                                                                                                                             |
| C                     | Cleared on read. This bit is cleared whenever the register is read.                                                                                                                                                                                                                        |
| UNP/SBZP              | Unpredictable or <i>Should Be Zero or Preserved</i> (SBZP). A read to this bit returns an Unpredictable value. It is written as 0 or preserved by writing the same value previously read from the same fields on the same processor. These bits are usually reserved for future expansion. |
| Core view             | This column defines the core access permission for a given bit.                                                                                                                                                                                                                            |
| External view         | This column defines the DBGTAP debugger view of a given bit.                                                                                                                                                                                                                               |
| Read/write attributes | This is used when the core and the DBGTAP debugger view are the same.                                                                                                                                                                                                                      |

On a power-on reset, all the CP14 debug registers take the values indicated by the Reset value column in the register bitfield definition tables (Table 13-4 on page 13-10, Table 13-6 on page 13-15, Table 13-9 on page 13-18, Table 13-10 on page 13-21, and Table 13-11 on page 13-22). In these tables, - means an Undefined reset value.

#### 13.3.1 Accessing debug registers

To access the CP14 debug registers you must set Opcode\_1 and CRn to 0. The Opcode\_2 and CRm fields of the coprocessor instructions are used to encode the CP14 debug register number, where the register number is {<Opcode2>, <CRm>}.

Table 13-2 on page 13-7 shows the CP14 debug register map. All of these registers are also accessible as scan chains from the DBGTAP.

Table 13-2 CP14 debug register map

| Binary address |             | Register number | CP14 debug register name          | Abbreviation      |
|----------------|-------------|-----------------|-----------------------------------|-------------------|
| Opcode_2       | CRm         |                 |                                   |                   |
| b000           | b0000       | c0              | Debug ID Register                 | DIDR              |
| b000           | b0001       | c1              | Debug Status and Control Register | DSCR              |
| b000           | b0010-b0100 | c2-c4           | Reserved                          | -                 |

| b001-b011      | b0000-b1111 | c16-c63         | Reserved                          | -                 |
| b100           | b0000-b0101 | c64-c69         | Breakpoint Value Registers        | BVRy <sup>a</sup> |
|                | b0110-b1111 | c70-c79         | Reserved                          | -                 |
| b101           | b0000-b0101 | c80-c85         | Breakpoint Control Registers      | BCRy <sup>a</sup> |
|                | b0110-b1111 | c86-c95         | Reserved                          | -                 |
| b110           | b0000-b0001 | c96-c97         | Watchpoint Value Registers        | WVRy <sup>a</sup> |
|                | b0010-b1111 | c98-c111        | Reserved                          | -                 |
| b111           | b0000-b0001 | c112-c113       | Watchpoint Control Registers      | WCRy <sup>a</sup> |
|                | b0010-b1111 | c114-c127       | Reserved                          | -                 |

a. y is the decimal representation for the binary number CRm.

#### Note

All the debug resources required for Monitor debug-mode debugging are accessible through CP14 registers. For Halting debug-mode debugging some additional resources are required. See Chapter 14 *Debug Test Access Port*.

13.3.2 CP14 c0, Debug ID Register (DIDR)

The Debug ID Register is a read-only register that defines the configuration of debug registers in a system. The format of the Debug ID Register is shown in Figure 13-2.

Figure 13-2 Debug ID Register format

The ARM1156T2F-S r0p4 processor has 0x1511x04 in this register.

The bitfield definitions for the Debug ID Register are shown in Table 13-3.

Table 13-3 Debug ID Register bitfield definition

| Bits                | Read/write attributes | Description                                                                                                                                                                                                                                                                                                                |

| [23: 20]<br>Context | R                     | Number of Breakpoint Register Pairs with Context ID comparison capability:<br>b0000 = 1 BRP has Context ID comparison capability<br>b0001 = 2 BRPs have Context ID comparison capability<br>...<br>b1111 = 16 BRPs have Context ID comparison capability.<br>For the ARM1156T2F-S processor these bits are b0001 (2 BRPs). |
| [19:16]<br>Version  | R                     | Debug architecture version. 0x1 denotes v6.                                                                                                                                                                                                                                                                                |

Table 13-3 Debug ID Register bitfield definition (continued)

| Bits                | Read/write attributes | Description                                                                              |
|---------------------|-----------------------|------------------------------------------------------------------------------------------|
| [15:12]<br>Revision | R                     | Debug architecture revision. 0x0 denotes revision 0.                                     |
| [11:8]              | UNP/SBZP              | Reserved.                                                                                |
| [7: 4]<br>Variant   | R                     | Implementation-defined variant number. This number is incremented on functional changes. |
| [3: 0]<br>Revision  | R                     | Implementation-defined revision number. This number is incremented on bug fixes.         |

The values of the following fields of the Debug ID Register agree with the values in CP15 c0, ID Register:

- DIDR[3:0] is the same as CP15 c0 bits [3:0]
- DIDR[7:4] is the same as CP15 c0 bits [23:20].

See *c1, Control Register* on page 3-46 for a description of CP15 c0, ID Register.

The reason for duplicating these fields here is that the Debug ID Register is accessible through scan chain 0. This enables an external debugger to determine the variant and revision numbers without stopping the core.

### 13.3.3 CP14 c1, Debug Status and Control Register (DSCR)

The Debug Status And Control Register contains status and configuration information about the state of the debug system. The format of the Debug Status And Control Register is shown in Figure 13-3 on page 13-10.

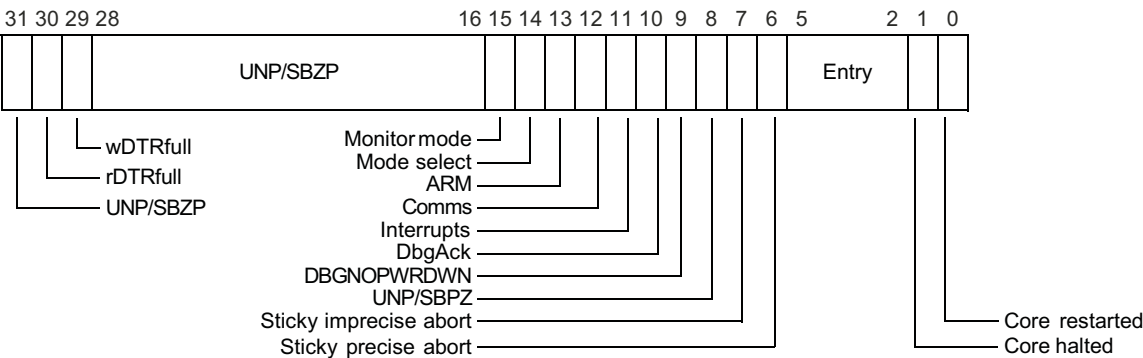

Figure 13-3 Debug Status And Control Register format

The bitfield definitions for the Debug Status And Control Register are shown in Table 13-4.

Table 13-4 Debug Status And Control Register bitfield definitions

| Bits    | Core view | External view | Reset value | Description                                                                                                                                                                                                                                                        |

| [13] | R         | RW            | 0           | Execute ARM instruction enable bit:<br>0 = Disabled<br>1 = Enabled.<br><br>If this bit is set, the core can be forced to execute ARM instructions in Debug state using the Debug Test Access Port. If this bit is set when the core is not in Debug state, the behavior of the ARM1156T2F-S processor is Unpredictable.                                                                                                                                                                                                                                         |
| [12] | RW        | R             | 0           | User mode access to communications channel control bit:<br>0 = User mode access to communications channel enabled<br>1 = User mode access to communications channel disabled.<br><br>If this bit is set and a User mode process tries to access the DIDR, DSCR, or the DTR, the Undefined instruction exception is taken. Because accessing the rest of CP14 debug registers is never possible in User mode, see <i>Executing CP14 debug instructions</i> on page 13-26, setting this bit means that a User mode process cannot access any CP14 debug register. |
| [11] | R         | RW            | 0           | Interrupts bit:<br>0 = Interrupts enabled<br>1 = Interrupts disabled. |------|-----------|---------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [0]  | R         | R             | 0           | <p>Core halted bit:</p> <p>0 = the processor is in normal state</p> <p>1 = the processor is in Debug state.</p> <p>The DBGTAP debugger can poll this bit to determine when the processor has entered Debug state. See <i>Debug state</i> on page 13-35 for a definition of Debug state.</p> |

- a. Bits DSCR[11:10] can be controlled by a DBGTAP debugger to execute code in normal state as part of the debugging process. For example, if the DBGTAP debugger has to execute an OS service to bring a page from disk into memory, and then return to the application to see the effect this change of state produces, it is undesirable that interrupts are serviced during execution of this routine.

Bits [5:2] are set to indicate:

- the reason for jumping to the Prefetch or Data Abort vector
- the reason for entering Debug state.

Using bits [5:2], a Prefetch Abort or a Data Abort handler determines if it must jump to the monitor target. Additionally, a DBGTAP debugger or monitor target can determine the specific debug event that caused the Debug state or debug exception entry.

### 13.3.4 CP14 c5, Data Transfer Registers (DTR)

This register consists of two separate physical registers:

- the rDTR (Read Data Transfer Register)
- the wDTR (Write Data Transfer Register).

The register accessed is dependent on the instruction used:

- writes, MCR and LDC instructions, access the wDTR
- reads, MRC and STC instructions, access the rDTR.

———— **Note** ————

Read and write refer to the core view.

For details of the use of these registers with the rDTRfull flag and wDTRfull flag see *Debug communications channel* on page 13-39. The format of both the rDTR and wDTR is shown in Figure 13-4 on page 13-14.

Figure 13-4 DTR format

The bitfield definitions for rDTR and wDTR are shown in Table 13-5.

Table 13-5 Data Transfer Register bitfield definitions

| Bits   | Core view | External view | Description                               |
|--------|-----------|---------------|-------------------------------------------|
| [31:0] | R         | W             | Read data transfer register (read-only)   |
| [31:0] | W         | R             | Write data transfer register (write-only) |

13.3.5 CP14 c6, Watchpoint Fault Address Register (WFAR)

The purpose of the *Watchpoint Fault Address Register* (WFAR) is to hold the address of the instruction that causes the watchpoint.

The register WFAR is:

- in CP14, c6
- a 32-bit read/write register
- accessible in privileged modes only.

When a watchpoint occurs in:

- ARM state, the WFAR contains the address of the instruction causing it plus 0x8.
- Thumb state, the WFAR contains the address of the instruction causing it plus 0x4.

To use the Watchpoint Fault Address Register read or write CP14 with:

- Opcode\_1 set to 0
- CRn set to c0
- CRm set to c6
- Opcode\_2 set to 0.

For example:

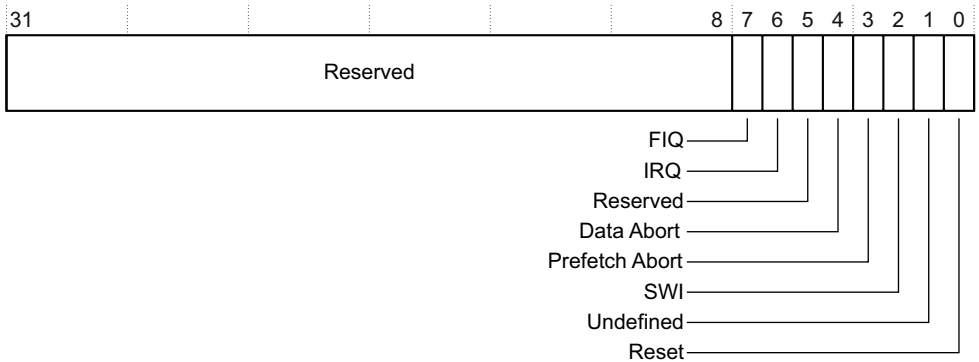

```
MRC p14, 0, <Rd>, c0, c6, 0; Read Watchpoint Fault Address Register
MCR p14, 0, <Rd>, c0, c6, 0; Write Watchpoint Fault Address Register
```

A write to CP14 c0 with Opcode\_2 set to 0 sets the WFAR to the value of the data written. This is useful for a debugger to restore the value of the WFAR.

A read to CP14 c0 returns the *Watchpoint Fault Address Register* (WFAR).

### 13.3.6 CP14 c7, Vector Catch Register (VCR)

The ARM1156T2F-S processor supports efficient exception vector catching. This is controlled by the VCR, as shown in Figure 13-5.

**Figure 13-5 Vector Catch Register format**

If one of the bits in this register is set and the corresponding vector is committed for execution, then a Debug exception or Debug state entry might be generated, depending on the value of the DSCR[15:14] bits (see *Behavior of the processor on debug events* on page 13-29). Under this model, any kind of fetch of an exception vector can trigger a vector catch, including the ones caused by exception entries.

The update of the VCR might occur several instructions after the corresponding MCR instruction. It only takes effect by the next *Instruction Memory Barrier* (IMB).

Table 13-6 shows the bitfield definitions for the Vector Catch Register.

**Table 13-6 Vector Catch Register bitfield definitions**

| Bits    | Normal address                       | High vector address                  | Description              | Read/write attributes | Reset value |
|---------|--------------------------------------|--------------------------------------|--------------------------|-----------------------|-------------|

| [2] SVC            | 0x00000008     | 0xFFFF0008          | Vector catch enable, SVC                   | RW                    | 0           |
| [1] Undefined      | 0x00000004     | 0xFFFF0004          | Vector catch enable, Undefined Instruction | RW                    | 0           |
| [0 Reset]          | 0x00000000     | 0xFFFF0000          | Vector catch enable, Reset                 | RW                    | 0           |

- a. You can configure the ARM1156T2F-S processor so that the IRQ uses vector exceptions other than 0x00000018 and 0xFFFF0018. See *Changes to existing interrupt vectors* on page 2-20 for more details.

### 13.3.7 CP14 c64-c69, Breakpoint Value Registers (BVR)

Each BVR is associated with a BCR register. BCR<sub>y</sub> is the corresponding control register for BVR<sub>y</sub>.

A pair of breakpoint registers, BVR<sub>y</sub>/BCR<sub>y</sub>, is called a *Breakpoint Register Pair* (BRP). BVR0-5 are paired with BCR0-5 to make BRP0-5.

The BVR of a BRP is loaded with an instruction address and then its contents can be compared against the instruction address bus of the processor.

The breakpoint value contained in the BVR corresponds to either an instruction address or a Context ID. Breakpoints can be set on:

- an instruction address
- a Context ID
- an instruction address/Context ID pair.

The ARM1156T2F-S processor supports thread-aware breakpoints and watchpoints. A Context ID can be loaded into the BVR and the BCR can be configured so this BVR value is compared against the CP15 Context ID Register, c13, instead of the instruction address bus. Another register pair loaded with an instruction address or data address can then be linked with the Context ID holding BRP. A breakpoint or watchpoint debug event is only generated if both the address and the Context ID match at the same time. This means that unnecessary hits can be avoided when debugging a specific thread within a task.

Breakpoint debug events generated on Context ID matches only are also supported. However, if the match occurs while the processor is running in a privileged mode and the debug logic in Monitor debug-mode, it is ignored. This is to avoid the processor ending in an unrecoverable state.

The ARM1156T2F-S processor implements the breakpoint and watchpoint registers shown in Table 13-7.

**Table 13-7 ARM1156T2F-S breakpoint and watchpoint registers**

| Binary address |             | Register number | CP14 debug register name         | Abbreviation | Context ID capable? |
|----------------|-------------|-----------------|----------------------------------|--------------|---------------------|

| b111           | b0000-b0001 | c112-c113       | Watchpoint Control Registers 0-1 | WCR0-1       | -                   |
|                | b0010-b1111 | c114-c127       | Reserved                         | -            | -                   |

The bitfield definitions for Context ID and nonContext ID Breakpoint Value Registers are shown in Table 13-8.

**Table 13-8 Breakpoint Value Registers, bitfield definition**

| Context ID capable? | Bits   | Read/write attributes | Description        |
|---------------------|--------|-----------------------|--------------------|
| No                  | [31:2] | RW                    | Breakpoint address |
| Yes                 | [31:0] | RW                    | Breakpoint address |

When a Context ID capable BRP is set for instruction address comparison, BVR bits [1:0] are ignored.

13.3.8 CP14 c80-c85, Breakpoint Control Registers (BCR)

These registers contain the necessary control bits for setting:

- breakpoints
- linked breakpoints.

The format of the Breakpoint Control Registers is shown in Figure 13-6.

Figure 13-6 Breakpoint Control Registers, format

Table 13-9 shows the bitfield definitions for the Breakpoint Control Registers.

Table 13-9 Breakpoint Control Registers, bitfield definitions

| Bits               | Value | Description                                                                                                                                                                                                                              | Read/write attributes | Reset value |
|--------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|-------------|
| [31:22] Reserved   | -     | UNP/SBZP                                                                                                                                                                                                                                 | UNP/SBZP              | -           |
| [21] M             | 0     | The instruction bus is compared against the corresponding BVR[31:3] and BCR[8:5]. The breakpoint matches only if these match.                                                                                                            | RW                    | -           |
|                    | 1     | The CP15 Context ID, register 13, is compared against corresponding BVR[31:0]. The breakpoint matches only if these match.                                                                                                               |                       |             |
| [20] E             | 0     | Link disabled.                                                                                                                                                                                                                           | RW                    | -           |
|                    | 1     | Link enabled.                                                                                                                                                                                                                            |                       |             |
| [19:16] Linked BRP | -     | Indicate another BRP to link this one with. Linked BRP number. The binary number encoded here indicates another BRP to link this one with. If a BRP is linked with itself, it is Unpredictable if a breakpoint debug event is generated. | RW                    | -           |

---

**Note**

---

The BCR[8:5] and BCR[2:1] fields still apply when a BRP is set for Context ID comparison. See *Setting breakpoints, watchpoints, and vector catch debug events* on page 13-41 for more information on programming sequences for linked breakpoints and linked watchpoints.

---

The following rules apply to the ARM1156T2F-S processor for breakpoint debug event generation:

- The update of a BVR or a BCR can take effect several instructions after the corresponding MCR. It takes effect by the next IMB.
- Updates of the CP15 Context ID Register c13, can take effect several instructions after the corresponding MCR. However, the write takes place by the end of the exception return. This is to ensure that a User mode process, switched in by a processor scheduler, can break at its first instruction.
- Any BRP holding an instruction address can be linked with any other one with Context ID capability. Several BRPs holding instruction addresses can be linked with the same Context ID capable one.
- If a BRP (holding an instruction address) is linked with one that is not configured for Context ID comparison and linking, it is Unpredictable whether a breakpoint debug event is generated or not. BCR[22:20] fields of the second BRP must be set to b011.
- If a BRP (holding an instruction address) is linked with one that is not implemented, it is Unpredictable if a breakpoint debug event is generated or not.
- If a BRP is linked with itself, it is Unpredictable if a breakpoint debug event is generated or not.
- If a BRP (holding an instruction address) is linked with another BRP (holding a Context ID value), and they are not both enabled (both BCR[0] bits set), the first one does not generate any breakpoint debug event.

### 13.3.9 CP14 c96-c97, Watchpoint Value Registers (WVR)

Each WVR is associated with a WCR register. WCR<sub>y</sub> is the corresponding register for WVR<sub>y</sub>.

A pair of watchpoint registers, WVR<sub>y</sub> and WCR<sub>y</sub>, is called a *Watchpoint Register Pair* (WRP). WVR0-1 are paired with WCR0-1 to make WRP0-1.

Watchpoints can be set on:

- a data address
- a data address/Context ID pair.

For the second case a WRP and a BRP with Context ID comparison capability have to be linked. A debug event is generated when both the data address and the Context ID pair match simultaneously. Table 13-10 shows the bitfield definitions for the Watchpoint Value Registers.

**Table 13-10 Watchpoint Value Registers, bitfield definitions**

| Bits   | Read/write attributes | Reset value | Description        |
|--------|-----------------------|-------------|--------------------|
| [31:2] | RW                    | -           | Watchpoint address |

### 13.3.10 CP14 c112-c113, Watchpoint Control Registers (WCR)

These registers contain the necessary control bits for setting:

- watchpoints
- linked watchpoints.

The format of the Watchpoint Control Registers is shown in Figure 13-7.

**Figure 13-7 Watchpoint Control Registers, format**

Bitfield definitions for the Watchpoint Control Registers are shown in Table 13-11.

Table 13-11 Watchpoint Control Registers, bitfield definitions

| Bits                                                                                                                                                                                                                                                                                                                                                                                                                       | Value | Description                                                                                                                                                              | Read/write attributes | Reset value |

|       | b10   | User                                                                                                                                                                                                                                                                 |                       |             |
|       | b11   | Either                                                                                                                                                                                                                                                               |                       |             |
|       |       | Determines what level of privilege the watchpoint acts on.                                                                                                                                                                                                           |                       |             |
| [0]   | 0     | Watchpoint disabled                                                                                                                                                                                                                                                  | RW                    | 0           |
|       | 1     | Watchpoint enabled.                                                                                                                                                                                                                                                  |                       |             |

In addition to the rules for breakpoint debug event generation, see *CP14 c80-c85, Breakpoint Control Registers (BCR)* on page 13-18, the following rules apply to the ARM1156T2F-S processor for watchpoint debug event generation:

- The update of a WVR or a WCR can take effect several instructions after the corresponding MCR. It only guaranteed to have taken effect by the next IMB.
- Any WRP can be linked with any BRP with Context ID comparison capability. Several BRPs (holding instruction addresses) and WRPs can be linked with the same Context ID capable BRP.
- If a WRP is linked with a BRP that is not configured for Context ID comparison and linking, it is Unpredictable if a watchpoint debug event is generated or not. BCR[22:20] fields of the BRP must be set to b111.
- If a WRP is linked with a BRP that is not implemented, it is Unpredictable if a watchpoint debug event is generated or not.
- If a WRP is linked with a BRP and they are not both enabled (BCR[0] and WCR[0] set), it does not generate a watchpoint debug event.

## 13.4 CP14 registers reset

The CP14 debug registers are all reset by the ARM1156T2F-S processor power-on reset signal, **nPORESETIN**, see *Power-on reset* on page 9-4.

This ensures that a vector catch set on the reset vector is taken when **nRESETIN** is deasserted. It also ensures that the DBGTAP debugger can be connected when the processor is running without clearing CP14 debug setting, because **DBGnTRST** does not reset these registers.

## 13.5 CP14 debug instructions

The CP14 debug instructions are shown in Table 13-12.

**Table 13-12 CP14 debug instructions**

| Binary address |             | Register number | Abbreviation    | Legal instructions                                                                                                                                       |
|----------------|-------------|-----------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|

| b100           | b0000-b1111 | 64-79           | BVR             | MRC p14, 0, <Rd>, c0, cy, 4 <sup>ab</sup><br>MCR p14, 0, <Rd>, c0, cy, 4 <sup>ab</sup>                                                                   |
| b101           | b0000-b1111 | 80-95           | BCR             | MRC p14, 0, <Rd>, c0, cy, 5 <sup>ab</sup><br>MCR p14, 0, <Rd>, c0, cy, 5 <sup>ab</sup>                                                                   |
| b110           | b0000-b1111 | 96-111          | WVR             | MRC p14, 0, <Rd>, 0, cy, 6 <sup>ab</sup><br>MCR p14, 0, <Rd>, 0, cy, 6 <sup>ab</sup>                                                                     |
| b111           | b0000-b1111 | 112-127         | WCR             | MRC p14, 0, <Rd>, 0, cy, 6 <sup>ab</sup><br>MCR p14, 0, <Rd>, 0, cy, 6 <sup>ab</sup>                                                                     |

a. <Rd> is any of R0-R14 ARM registers.

b. y is the decimal representation for the binary number CRm.

In Table 13-12, MRC p14,0,<Rd>, c0, c5, 0 and STC p14, c5, <addressing mode> refer to the rDTR and MCR p14,0,<Rd>, c0, c5, 0 and LDC p14, c5, <addressing mode> refer to the wDTR. See *CP14 c5, Data Transfer Registers (DTR)* on page 13-13 for more details.

The MRC p14, 0, R15, c0, c1, 0 instruction sets the CPSR flags as follows:

- N flag = DSCR[31]. This is an Unpredictable value.
- Z flag = DSCR[30]. This is the value of the rDTRfull flag.
- C flag = DSCR[29]. This is the value of the wDTRfull flag.
- V flag = DSCR[28]. This is an Unpredictable value.

Instructions that follow the MRC instruction can be conditioned to these CPSR flags.

### 13.5.1 Executing CP14 debug instructions

If the core is in Debug state (see *Debug state* on page 13-35), you can execute any CP14 debug instruction regardless of the processor mode.

If the processor tries to execute a CP14 debug instruction that either is not in Table 13-12 on page 13-25, or is targeted to a reserved register, such as a non-implemented BVR, the Undefined instruction exception is taken.

You can access the DCC (read DIDR, read DSCR and read/write DTR) in User mode. All other CP14 debug instructions are privileged. If the processor tries to execute one of these in User mode, the Undefined instruction exception is taken.

If the User mode access to DCC disable bit, DSCR[12], is set, all CP14 debug instructions are considered as privileged, and all attempted User mode accesses to CP14 debug registers generate an Undefined instruction exception.

When DSCR bit 14 is set (Halting debug-mode selected and enabled), if the software running on the processor tries to access any register other than the DIDR, the DSCR, or the DTR, the core takes the Undefined instruction exception. The same thing happens if the core is not in any Debug mode (DSCR[15:14]=b00).

This lockout mechanism ensures that the software running on the core cannot modify the settings of a debug event programmed by the DBGTap debugger.

Table 13-13 on page 13-27 shows the results of executing CP14 debug instructions.

Table 13-13 Debug instruction execution

| State when executing CP14 debug instruction: |             |                                         |                                       | Results of CP14 debug instruction execution: |                     |                            |
|----------------------------------------------|-------------|-----------------------------------------|---------------------------------------|----------------------------------------------|---------------------|----------------------------|
| Processor mode                               | Debug state | DSCR[15:14] (Mode enabled and selected) | DSCR[12] (DCC User accesses disabled) | Read DIDR, read DSCR and read/ write DTR     | Write DSCR          | Read/write other registers |
| x                                            | Yes         | xx                                      | x                                     | Proceed                                      | Proceed             | Proceed                    |
| User                                         | No          | xx                                      | 0                                     | Proceed                                      | Undefined exception | Undefined exception        |
| User                                         | No          | xx                                      | 1                                     | Undefined exception                          | Undefined exception | Undefined exception        |
| Privileged                                   | No          | b00 (None)                              | x                                     | Proceed                                      | Proceed             | Undefined exception        |
| Privileged                                   | No          | b01 (Halt)                              | x                                     | Proceed                                      | Proceed             | Undefined exception        |
| Privileged                                   | No          | b10 (Monitor)                           | x                                     | Proceed                                      | Proceed             | Proceed                    |
| Privileged                                   | No          | b11 (Halt)                              | x                                     | Proceed                                      | Proceed             | Undefined exception        |

## 13.6 Debug events

A debug event is any of the following:

- *Software debug event*
- *External debug request signal* on page 13-29
- *Halt DBGTAP instruction* on page 13-29.

### 13.6.1 Software debug event

A software debug event is any of the following:

- A watchpoint debug event. This occurs when:
  - the data address present in the data bus matches the watchpoint value
  - all the conditions of the WCR match
  - the watchpoint is enabled
  - the linked Context ID-holding BRP (if any) is enabled and its value matches the Context ID in CP15 c13.
- A breakpoint debug event. This occurs when:
  - an instruction was fetched and the instruction address present in the instruction bus matched the breakpoint value
  - at the same time the instruction was fetched, all the conditions of the BCR matched
  - the breakpoint was enabled
  - at the same time the instruction was fetched, the linked Context ID-holding BRP (if any) was enabled and its value matched the Context ID in CP15 c13
  - the instruction is now committed for execution.
- A breakpoint debug event also occurs when:
  - an instruction was fetched and the CP15 Context ID (register 13) matched the breakpoint value
  - at the same time the instruction was fetched, all the conditions of the BCR matched
  - the breakpoint was enabled
  - the instruction is now committed for execution.
- A software breakpoint debug event. This occurs when a BKPT instruction is committed for execution.

- A vector catch debug event. This occurs when:
  - The instruction at a vector location was fetched. This includes any kind of prefetches, and ones caused by exception entries.
  - At the same time the instruction was fetched, the corresponding bit of the VCR was set (vector catch enabled).
  - The instruction is now committed for execution.

### 13.6.2 External debug request signal

The ARM1156T2F-S processor has an external debug request input signal, **EDBGRQ**. When this signal is HIGH it causes the processor to enter Debug state when execution of the current instruction has completed. When this happens, the DSCR[5:2] method of entry bits are set to b0100.

This signal can be driven by the ETM to signal a trigger to the core. For example, if the processor is in Halting debug-mode and a memory permission fault occurs, an external Trace analyzer can collect trace information around this trigger event at the same time that the processor is stopped to examine its state. See the *Chapter 15 Trace Interface Port* for more details. A DBGTAP debugger can also drive this signal.

### 13.6.3 Halt DBGTAP instruction

The Halt mechanism is used by the Debug Test Access Port to force the core into Debug state. When this happens, the DSCR[5:2] method of entry bits are set to b0000.

### 13.6.4 Behavior of the processor on debug events

This section describes how the processor behaves on debug events while not in Debug state. See *Debug state* on page 13-35 for information on how the processor behaves while in Debug state.

When a software debug event occurs and Monitor debug-mode is selected and enabled then a Debug exception is taken. However, Prefetch Abort and Data Abort Vector catch debug events are ignored. This is to avoid the processor ending in an unrecoverable state on certain combinations of exceptions and vector catches. Unlinked Context ID breakpoint debug events are also ignored if the processor is running in a privileged mode and Monitor debug-mode is selected and enabled. The external debug request signal and the Halt DBGTAP instruction are ignored when Monitor debug-mode is selected and enabled.

When a debug event occurs and Halting debug-mode is selected and enabled then the processor enters Debug state.

When neither Halt nor Monitor debug-mode is selected and enabled, all debug events are ignored, although the BKPT instruction generates a Prefetch Abort exception.

Table 13-14 Behavior of the processor on debug events

| DSCR[15:14] | Mode selected and enabled | Action on software debug event      | Action on external debug request signal activation | Action on Halt DBGTap |
|-------------|---------------------------|-------------------------------------|----------------------------------------------------|-----------------------|
| b00         | None                      | Ignore/Prefetch Abort <sup>a</sup>  | Ignore                                             | Ignore                |
| b01         | Halt                      | Debug state entry                   | Debug state entry                                  | Debug state entry     |
| b10         | Monitor                   | Debug exception/Ignore <sup>b</sup> | Ignore                                             | Ignore                |
| b11         | Halt                      | Debug state entry                   | Debug state entry                                  | Debug state entry     |

- a. When debug is disabled, a BKPT instruction generates a Prefetch Abort exception instead of being ignored.
- b. Prefetch Abort and Data Abort vector catch debug events are ignored in Monitor debug-mode. Unlinked Context ID breakpoint debug events are also ignored if the processor is running in a privileged mode and Monitor debug-mode is selected and enabled.

13.6.5 Behavior of the CPSR in Debug state

The CPSR is frozen on entry to Debug state, and the IT state bits do not advance when instructions are executed.

The CPSR can be read and written to in Debug state with the following instructions:

- MRS

This reads the entire CPSR, including the execution state bits that normally read as zero when not in Debug state.
- MSR

You can use the MSR instruction for setting the flags, mode, and exception mask bits in the CPSR. The instruction behaves as if it were executed in a privileged mode. You must not use to modify the execution state bits, doing so results in Unpredictable behavior.
- BX

You can use the BX instruction to set or clear the T bit in the CPSR.

SPSR to CPSR transfers

- Data processing instructions with the S instruction bit set to 1'b1, and PC as the target, can simultaneously:
- set the entire CPSR
  - write to the PC.

### 13.6.6 Effect of a debug event on CP15 registers

The four CP15 registers that can be set on a debug event are:

- *Instruction Fault Status Register (IFSR)*
- *Data Fault Status Register (DFSR)*
- *Fault Address Register (FAR)*
- *Watchpoint Fault Address Register (WFAR).*

They are set under the following circumstances:

- The IFSR is set whenever a breakpoint, software breakpoint, or vector catch debug event generates a Debug exception entry. It is set to indicate the cause for the Prefetch Abort vector fetch.
- The DFSR is set whenever a watchpoint debug event generates a Debug exception entry. It is set to indicate the cause for the Data Abort vector fetch.
- The ARM1156T2F-S processor updates the FAR on debug exception entry because of watchpoints, although this is architecturally Unpredictable. It is set to the address that triggered the watchpoint.
- The WFAR is set whenever a watchpoint debug event generates either a Debug exception or Debug state entry. It is set to the address of the instruction that caused the Watchpoint debug event, plus an offset dependent on the processor state. These offsets are the same as the ones shown in Table 13-17 on page 13-36.

Table 13-15 shows the setting of CP15 registers on debug events.

**Table 13-15 Setting of CP15 registers on debug events**

| Register | Debug exception taken caused by:                               |                          | Debug state entry caused by:          |                          |
|----------|----------------------------------------------------------------|--------------------------|---------------------------------------|--------------------------|
|          | A breakpoint, software breakpoint, or vector catch debug event | A watchpoint debug event | A debug event other than a watchpoint | A watchpoint debug event |
| IFSR     | Cause of Prefetch Abort exception handler entry                | Unchanged                | Unchanged                             | Unchanged                |

Table 13-15 Setting of CP15 registers on debug events (continued)

| Register | Debug exception taken caused by:                               |                                                                            | Debug state entry caused by:          |                                                                            |
|----------|----------------------------------------------------------------|----------------------------------------------------------------------------|---------------------------------------|----------------------------------------------------------------------------|
|          | A breakpoint, software breakpoint, or vector catch debug event | A watchpoint debug event                                                   | A debug event other than a watchpoint | A watchpoint debug event                                                   |
| DFSR     | Unchanged                                                      | Cause of Data Abort exception handler entry                                | Unchanged                             | Unchanged                                                                  |
| FAR      | Unchanged                                                      | Watchpointed address                                                       | Unchanged                             | Unchanged                                                                  |
| WFAR     | Unchanged                                                      | Address <sup>a</sup> of the instruction causing the watchpoint debug event | Unchanged                             | Address <sup>a</sup> of the instruction causing the watchpoint debug event |

a. Offset by 0x8 for ARM state and 0x4 for Thumb state.

You must take care when setting a breakpoint or software breakpoint debug event inside the Prefetch Abort or Data Abort exception handlers, or when setting a watchpoint debug event on a data address that might be accessed by any of these handlers. These debug events overwrite the r14\_abt, SPRS\_abt and the CP15 registers listed in this section, leading to an unpredictable software behavior if the handlers did not have the chance of saving the registers.

## 13.7 Debug exception

When a Software debug event occurs and Monitor debug-mode is selected and enabled then a Debug exception is taken. Prefetch Abort and Data Abort Vector catch debug events are ignored though. Unlinked Context ID breakpoint debug events are also ignored if the processor is running in a privileged mode and Monitor debug-mode is selected and enabled. If the cause of the Debug exception is a watchpoint debug event, the processor performs the following actions:

- The DSCR[5:2] method of entry bits are set to indicate that a watchpoint occurred.
- The CP15 DFSR, FAR, and WFAR, are set as described in *Effect of a debug event on CP15 registers* on page 13-31.
- The same sequence of actions as in a Data Abort exception is performed. This includes setting the r14\_abt, base register and destination registers to the same values as if this was a Data Abort.

The Data Abort handler is responsible for checking the DFSR or DSCR[5:2] bit to determine if the routine entry was caused by a debug exception or a Data Abort exception. On entry:

1. It must first check for the presence of a monitor target.
2. If present, the handler must disable the active watchpoints. This is necessary to prevent corruption of the FAR because of an unexpected watchpoint debug event whilst servicing a Data Abort exception.
3. If the cause is a Debug exception the Data Abort handler branches to the monitor target.

### Note

- the watchpointed address is in the FAR
- the address, offset by 0x8 for ARM state and 0x4 for Thumb state, of the instruction that caused the watchpoint debug event is in the WFAR
- the address of the instruction to restart at plus 0x08 is in the r14\_abt register.

If the cause of the Debug exception is a breakpoint, software breakpoint or vector catch debug event, the processor performs the following actions:

- the DSCR[5:2] method of entry bits are set appropriately
- the CP15 IFSR register is set as described in *Effect of a debug event on CP15 registers* on page 13-31
- the same sequence of actions as in a Prefetch Abort exception is performed.

The Prefetch Abort handler is responsible for checking the IFSR or DSCR[5:2] bits to find out if the routine entry is caused by a Debug exception or a Prefetch Abort exception. If the cause is a Debug exception it branches to the monitor target.

———— **Note** ————

The address of the instruction causing the Software debug event plus 0x04 is in the r14\_abt register.

Table 13-16 shows the values in the link register after exceptions.

**Table 13-16 Values in the link register after exceptions**

| Cause of the fault | ARM  | Thumb | Return address (RA <sup>a</sup> ) meaning                                                                               |
|--------------------|------|-------|-------------------------------------------------------------------------------------------------------------------------|
| Breakpoint         | RA+4 | RA+4  | Breakpointed instruction address                                                                                        |
| Watchpoint         | RA+8 | RA+8  | Address of the instruction where the execution resumes (a number of instructions after the one that hit the watchpoint) |
| BKPT instruction   | RA+4 | RA+4  | BKPT instruction address                                                                                                |
| Vector catch       | RA+4 | RA+4  | Vector address                                                                                                          |
| Prefetch Abort     | RA+4 | RA+4  | Address of the instruction where the execution resumes                                                                  |
| Data Abort         | RA+8 | RA+8  | Address of the instruction where the execution resumes                                                                  |

a. This is the address of the instruction that the processor first executes on Debug state exit. Watchpoints can be imprecise. RA is not the address of the instruction after the one that hit the watchpoint, the processor might stop a number of instructions later. The address (offset by 0x8 for ARM state and 0x4 for Thumb state) of the instruction that hit the watchpoint is in the CP15 WFAR.

## 13.8 Debug state

When the conditions in *Behavior of the processor on debug events* on page 13-29 are met then the processor switches to Debug state. While in Debug state, the processor behaves as follows:

- The DSCR[0] core halted bit is set.
- The **DBGACK** signal is asserted, see *External signals* on page 13-49.
- The DSCR[5:2] method of entry bits are set appropriately.
- The CP15 IFSR, DFSR, and FAR registers are set as described in *Effect of a debug event on CP15 registers* on page 13-31. The WFAR is set to an Unpredictable value.
- The processor is halted. The pipeline is flushed and no instructions are fetched.
- The processor does not change the execution mode. The CPSR is not altered.
- Interrupts and exceptions are treated as described in *Interrupts* on page 13-37 and *Exceptions* on page 13-37.
- Software debug events are ignored.
- The external debug request signal is ignored.
- Debug state entry request commands are ignored.
- There is a mechanism, using the Debug Test Access Port, where the core is forced to execute an ARM state instruction. This mechanism is enabled using DSCR[13] execute ARM instruction enable bit.
- The core executes the instruction as if it is in ARM state, regardless of the actual value of the T bit of the CPSR. If you do set both the J and T bits the behavior is Unpredictable.
- In this state the core can execute any ARM state instruction, as if in a privileged mode. For example, if the processor is in User mode then the MSR instruction updates the PSRs and all the CP14 debug instructions can be executed. However, the processor still accesses the register bank and memory as indicated by the CPSR mode bits. For example, if the processor is in User mode then it sees the User mode register bank, and accesses the memory without any privilege.
- In Debug state, the CP15 System Performance Monitor Registers do not count events. Therefore the debugger does not write events to the ETM. The Cycle Count Register, CCNT, stops counting in Debug state.

- The PC behaves as described in *Behavior of the PC in Debug state*.
- A DBGTAP debugger can force the processor out of Debug state by issuing a Restart instruction, see Table 14-1 on page 14-6. The Restart command clears the DSCR[1] core restarted flag. When the processor has actually exited Debug state, the DSCR[1] core restarted bit is set and the DSCR[0] core halted bit and **DBGACK** signal are cleared.

### 13.8.1 Behavior of the PC in Debug state

In Debug state:

- The PC is frozen on entry to Debug state. That is, it does not increment on the execution of ARM instructions. However, branches and instructions that modify the PC directly do update it.
- If the PC is read after the processor has entered Debug state, it returns a value as described in Table 13-17, depending on the previous state and the type of debug event.
- If a sequence for writing a certain value to the PC is executed while in Debug state, and then the processor is forced to restart, execution starts at the address corresponding to the written value. However, the CPSR has to be set to the return ARM state or Thumb state before the PC is written to, otherwise the processor behavior is Unpredictable.
- If the processor is forced to restart without having performed a write to the PC, the restart address is Unpredictable.
- If the PC or CPSR are written to while in Debug state, subsequent reads to the PC return an Unpredictable value.
- If a conditional branch is executed and it fails its condition code, an Unpredictable value is written to the PC.

Table 13-17 shows the read PC value after Debug state entry for different debug events.

**Table 13-17 Read PC value after Debug state entry**

| Debug event      | ARM  | Thumb | Return address (RA <sup>a</sup> ) meaning                                                                           |
|------------------|------|-------|---------------------------------------------------------------------------------------------------------------------|
| Breakpoint       | RA+8 | RA+4  | Breakpointed instruction address                                                                                    |
| Watchpoint       | RA+8 | RA+4  | Address of the instruction where the execution resumes (several instructions after the one that hit the watchpoint) |
| BKPT instruction | RA+8 | RA+4  | BKPT instruction address                                                                                            |

Table 13-17 Read PC value after Debug state entry (continued)

| Debug event                              | ARM  | Thumb | Return address (RA <sup>a</sup> ) meaning              |
|------------------------------------------|------|-------|--------------------------------------------------------|
| Vector catch                             | RA+8 | RA+4  | Vector address                                         |
| External debug request signal activation | RA+8 | RA+4  | Address of the instruction where the execution resumes |
| Debug state entry request command        | RA+8 | RA+4  | Address of the instruction where the execution resumes |

- a. This is the address of the instruction that the processor first executes on Debug state exit. Watchpoints can be imprecise. RA is not the address of the instruction after the one that hit the watchpoint, the processor might stop a number of instructions later. The address (offset by 0x8 for ARM state and 0x4 for Thumb state) of the instruction that hit the watchpoint is in the CP15 WFIAR.

## 13.8.2 Interrupts

Interrupts are ignored regardless of the value of the I and F bits of the CPSR, although these bits are not changed because of the Debug state entry.

## 13.8.3 Exceptions

Exceptions are handled as follows while in Debug state:

**Reset** This exception is taken as in a normal processor state, ARM or Thumb. This means the processor leaves Debug state as a result of the system reset.

### Prefetch Abort

This exception cannot occur because no instructions are prefetched while in Debug state.

**Debug** This exception cannot occur because software debug events are ignored while in Debug state.

### SVC and Undefined exceptions

If one of these exception occurs while in Debug state the behavior of the ARM1156T2F-S processor is Unpredictable.

## Data abort

When a Data Abort occurs in Debug state, the behavior of the core is as follows:

- The PC, CPSR, and SPSR\_abt are set as for a normal processor state exception entry.
- If the debugger has not written to the PC or the CPSR while in Debug state, R14\_abt is set as described in the *ARM Architecture Reference Manual*.
- If the debugger has written to the PC or the CPSR while in Debug state, R14\_abt is set to an Unpredictable value.
- The processor remains in Debug state and does not fetch the exception vector.
- The DFSR, and FAR are set as for a normal processor state exception entry.
- The DSCR[6] sticky precise Data Abort bit, or the DSCR[7] sticky imprecise Data Aborts bit are set.
- The DSCR[5:2] method of entry bits are set to b0110.

If it is an imprecise Data Abort and the debugger has not written to the PC or CPSR, R14\_abt is set as described in the *Architecture Reference Manual*. Therefore the processor is in the same state as if the exception was taken on the instruction that was cancelled by the Debug state entry sequence. This is necessary because it is not possible to guarantee that the debugger reads the PC before an imprecise Data Abort exception is taken.

### 13.8.4 Behavior on the execution state bits in Debug state

In Debug state the execution state bits:

- are not advanced, and have no effect on executed instruction.
- are reset to 0 on branches
- are not altered on any data-processing instructions that write to the PC except when the S bit of the instruction is set
- are updated from SPSR on exception return instructions.

For more information see the *ARM Architecture Reference Manual*.

## 13.9 Debug communications channel

There are two ways that a DBGTAP debugger can send data to or receive data from the core:

- The debug communications channel, when the core is not in Debug state. It is defined as the set of resources used for communicating between the DBGTAP debugger and a piece of software running on the core.
- The mechanism for forcing the core to execute ARM instructions, when the core is in Debug state. For details see *Executing instructions in Debug state* on page 14-24.

At the core side, the debug communications channel resources are:

- CP14 Debug Register c5 (DTR). Data coming from a DBGTAP debugger can be read by an MRC or STC instruction addressed to this register. The core can write to this register any data intended for the DBGTAP debugger, using an MCR or LDC instruction. Because the DTR comprises both a read (rDTR) and a write portion (wDTR), a data item written by the core can be held in this register at the same time as one written by the DBGTAP debugger.
- Some flags and control bits of CP14 Debug Register c1 (DSCR):
  - User mode access to communications channel disable, DSCR[12]. If this bit is set, only privileged software is able to access the debug communications channel. That is, access the DSCR and the DTR.
  - wDTRfull flag, DSCR bit 29. When clear, this flag indicates to the core that the wDTR is ready to receive data. It is automatically cleared on reads of the wDTR by the DBGTAP debugger, and is set on writes by the core to the same register. If this bit is set and the core attempts to write to the wDTR, the register contents are overwritten and the wDTRfull flag remains set.
  - rDTRfull flag, DSCR bit 30. When set, this flag indicates to the core that there is data available to read at the rDTR. It is automatically set on writes to the rDTR by the DBGTAP debugger, and is cleared on reads by the core of the same register.

The DBGTAP debugger side of the debug communications channel is described in *Monitor debug-mode debugging* on page 14-50.

## 13.10 Debugging in a cached system

Debugging must be non-intrusive in a cached system. In ARM1156T2F-S systems, you can preserve the contents of the cache so the state of the target application is not altered, and to maintain memory coherency during debugging.

To preserve the contents of the level one cache, you can disable the instruction cache and data cache line fills so read misses from main memory do not update the caches. You can put the caches in this mode by programming the operation of the caches during debug using CP15 c15. See *c15, Cache Debug Control Register* on page 3-98. This facility is accessible from both the core and DBGTAP debugger sides.

In Debug state, the caches behave as follows, for memory coherency purposes:

- Cache reads behave as for normal operation.
- Writes are covered in *Data cache writes*.
- ARMv6 includes CP15 instructions for cleaning and invalidating the cache content, See *c7, Cache Operations Register* on page 3-66. These instructions enable you to reset the processor memory system to a known safe state, and are accessible from both the core and the DBGTAP debugger side.

### 13.10.1 Data cache writes

The problem with data cache writes is that, while debugging, you might want to write some instructions to memory, either some code to be debugged or a BKPT instruction. This poses coherency issues on the instruction cache.

In ARM1156T2F-S systems, CP15 c15, the Cache Debug Control Register, enables you to use the following features:

- You can put the processor in a state where data writes work as if the cache is enabled and every region of memory is write-through. This facility is accessible from both the core and the DBGTAP debugger side. See *c15, Data Cache Debug Register* on page 3-86.
- ARMv6 architecture provides CP15 instructions for invalidating the instruction cache, described in *c7, Cache Operations Register* on page 3-66 to ensure that, after a write, there are no out-of-date words in the instruction cache.

## 13.11 Monitor debug-mode debugging

Monitor debug-mode debugging is essential in real-time systems when the integer unit cannot be halted to collect information. Engine controllers and servo mechanisms in hard drive controllers are examples of systems that might not be able to stop the code without physically damaging components. These are typical systems that can be debugged using Monitor debug-mode.

For situations that can only tolerate a small intrusion into the instruction stream, Monitor debug-mode is ideal. Using this technique, code can be suspended with an exception long enough to save off state information and important variables. The code continues when the exception handler is finished. The *Method Of Entry* (MOE) bits in the DSCR can be read to determine what caused the exception.

When in Monitor debug-mode, all breakpoint and watchpoint registers can be read and written with MRC and MCR instructions from a privileged processing mode.

### 13.11.1 Entering the monitor target

No debug-mode is the selected default by on power-on reset. Monitor debug-mode must be selected after reset by setting DSCR[15]. When a software debug event occurs (as described in *Software debug event* on page 13-28) and Monitor debug-mode is selected and enabled, then a Debug exception is taken, although Prefetch Abort and Data Abort vector catch debug events are ignored. Debug exception entry is described in *Debug exception* on page 13-33. The Prefetch Abort handler can check the IFSR or the DSCR[5:2] bits, and the Data Abort handler can check the DFSR or the DSCR[5:2] bits, to find out the caused of the exception. If the cause was a Debug exception, the handler branches to the monitor target.

When the monitor target is running, it can determine and modify the processor state and new software debug events can be programmed.

### 13.11.2 Setting breakpoints, watchpoints, and vector catch debug events

When the monitor target is running, breakpoints, watchpoints, and vector catch debug events can be set. This can be done by executing MCR instructions to program the appropriate CP14 debug registers. The monitor target can only program these registers if the processor is in a privileged mode and Monitor debug-mode is selected and enabled, see *Debug Status And Control Register bitfield definitions* on page 13-10.

You can program a vector catch debug event using CP14 Debug Vector Catch Register.

You can program a breakpoint debug event using CP14 debug breakpoint value registers and CP14 Debug Breakpoint Control Registers, see *CP14 c64-c69, Breakpoint Value Registers (BVR)* on page 13-16 and *CP14 c80-c85, Breakpoint Control Registers (BCR)* on page 13-18.

You can program a watchpoint debug event using CP14 Debug Watchpoint Value Registers and CP14 Debug Watchpoint Control Registers, see *CP14 c96-c97, Watchpoint Value Registers (WVR)* on page 13-20, and *CP14 c112-c113, Watchpoint Control Registers (WCR)* on page 13-21.

### Setting a simple breakpoint on an instruction address

You can set a simple breakpoint on an instruction address as follows:

1. Read the BCR.
2. Clear the BCR[0] enable breakpoint bit in the read word and write it back to the BCR. Now the breakpoint is disabled.
3. Write the instruction address to the BVR register.
4. Write to the BCR with its fields set as follows:
  - BCR[22:21] is set to b00 to indicate that the value loaded into BVR is for comparison against the instruction address bus.
  - BCR[20] enable linking bit cleared, to indicate that this breakpoint is not to be linked.
  - BCR[8:5] byte address select BCR field as required.
  - BCR[2:1] privilege mode control BCR field as required.
  - BCR[0] enable breakpoint bit set.

#### ———— Note ————

Any BVR can be compared against the instruction address bus.

---

### Setting a simple breakpoint on a Context ID value

A simple breakpoint on a Context ID value can be set, using one of the Context ID capable BRPs, as follows:

1. Read the BCR.
2. Clear the BCR[0] enable breakpoint bit in the read word and write it back to the BCR. Now the breakpoint is disabled.

3. Write the Context ID value to the BVR register.
4. Write to the BCR with its fields set as follows:
  - BCR[22:21] set to b01 to indicate that the value loaded into BVR is for comparison against the CP15 Context ID Register c13.
  - BCR[20] enable linking bit cleared, to indicate that this breakpoint is not to be linked.
  - BCR[8:5] byte address select BCR field set to b1111.
  - BCR[2:1] privilege mode control BCR field as required.
  - BCR[0] enable breakpoint bit set.

---

**Note**

---

Any BVR can be compared against the instruction address bus.

---

### Setting a linked breakpoint

In the following sequence b is any of the breakpoint registers pairs with Context ID comparison capability, and a is any of the implemented breakpoints different from b. You can link instruction address holding and Context ID-holding breakpoints register pairs as follows:

1. Read the BCRa and BCRb.
2. Clear the BCRa[0] and BCRb[0] enable breakpoint bits in the read words and write them back to the BCRs. Now the breakpoints are disabled.
3. Write the instruction address to the BVRa register.
4. Write the Context ID to the BVRb register.
5. Write to the BCRb with its fields set as follows:
  - BCRb[22:21] is set to b01 to indicate that the value loaded into BVRb is for comparison against the CP15 Context ID Register 13
  - BCRb[20] enable linking bit, set
  - BCRb[8:5] byte address select set to b1111
  - BCRb[2:1] privilege mode control set to b11
  - BCRb[0] enable breakpoint bit set.
6. Write to the BCRa with its fields set as follows:
  - BCRa[22:21] is set to b00 to indicate that the value loaded into BVRa is for comparison against the instruction address bus

- BCRa[20] enable linking bit set, to link this BRP with the one indicated by BCRa[19:16] (BRPb in this example)
- binary representation of b into BCR[19:6] linked BRP field
- BCRa[8:5] byte address select field as required
- BCRa[2:1] privilege mode control field as required
- BCRa[0] enable breakpoint set.

### Setting a simple watchpoint

You can set a simple watchpoint as follows:

1. Read the WCR.
2. Clear the WCR[0] enable watchpoint bit in the read word and write it back to the WCR. Now the watchpoint is disabled.
3. Write the data address to the WVR register.
4. Write to the WCR with its fields set as follows:
  - WCR[20] enable linking bit cleared, to indicate that this watchpoint is not to be linked
  - WCR byte address select, load/store access, and privilege mode control fields as required
  - WCR[0] enable watchpoint bit set.

#### ———— Note ————

Any WVR can be compared against the data address bus.

---

### Setting a linked watchpoint

In the following sequence b is any of the BRPs with Context ID comparison capability. You can use any of the WRP. You can link WRP and Context ID-holding BRPs as follows:

1. Read the WCR and BCRb.
2. Clear the WCR[0] Enable Watchpoint and the BCRb[0] Enable breakpoint bits in the read words and write them back to the WCR and BCRb. Now the watchpoint and the breakpoint are disabled.
3. Write the data address to the WVR register.
4. Write the Context ID to the BVRb register.

5. Write to the WCR with its fields set as follows:
  - WCR[20] enable linking bit set, to link this WRP with the BRP indicated by WCR[19:16] (BRPb in this example)
  - Binary representation of b into WCR[19:6] linked BRP field
  - WCR byte address select, load/store access, and privilege mode control fields as required
  - WCR[0] enable watchpoint bit set.
6. Write to the BCRb with its fields set as follows:
  - BCRb[21] meaning of BVR bit set, to indicate that the value loaded into BVRb is to be compared against the CP15 Context ID Register.
  - BCRb[20] enable linking bit, set
  - BCRb[8:5] byte address select set to b1111
  - BCRb[2:1] privilege mode control set to b11
  - BCRb[0] enable breakpoint bit set.

### 13.11.3 Setting software breakpoint debug events (BKPT)

To set a software breakpoint on a particular physical address, the monitor target must perform the following steps:

1. Read memory location and save actual instruction.
2. Write BKPT instruction to the memory location.
3. Read memory location again to check that the BKPT instruction has been written.
4. If it has not been written, determine the reason.

#### Note

Cache coherency issues might arise when writing a BKPT instruction. See *Debugging in a cached system* on page 13-40.

### 13.11.4 Using the debug communications channel

To read a word sent by a DBGTap debugger:

1. Read the DSCR register.
2. If DSCR[30] rDTRfull flag is clear, then go to 1.
3. Read the word from the rDTR, CP14 Debug Register c5.

To write a word for a DBGTap debugger:

1. Read the DSCR register.

2. If DSCR[29] wDTRfull flag is set, then go to 1.
3. Write the word to the wDTR, CP14 Debug Register c5.

## 13.12 Halting debug-mode debugging

Halting debug-mode is used to debug the processor using external hardware connected to the DBGTAP. The external hardware provides an interface to a DBGTAP debugger application. You can only select Halting debug-mode by setting the halt bit (bit 14) of the DSCR, which is only writable through the Debug Test Access Port. See Chapter 14 *Debug Test Access Port*.

In Halting debug-mode the processor stops executing instructions if one of the following events occurs:

- a breakpoint hits
- a watchpoint hits
- a BKPT instruction is executed
- the **EDBGRQ** signal is asserted
- a Halt instruction has been scanned into the DBGTAP instruction register
- an vector catch occurs.

When the processor is halted, it is controlled by sending instructions to the integer unit through the DBGTAP. Any valid instruction can be scanned into the processor, and the effect of the instruction upon the integer unit is as if it was executed under normal operation. Also accessible through the DBGTAP is a register to transfer data between CP14 and the DBGTAP debugger.

The integer unit is restarted by executing a DBGTAP Restart instruction.

### 13.12.1 Entering Debug state

When a debug event occurs and Halting debug-mode is selected and enabled then the processor enters Debug state as defined in *Debug state* on page 13-35.

When the core is in Debug state, the DBGTAP debugger can determine and modify the processor state and new debug events can be programmed.

### 13.12.2 Exiting Debug state

You can force the processor out of Debug state using the DBGTAP Restart instruction. See *Exiting Debug state* on page 14-5. The DSCR[1] core restarted bit indicates if the core has already returned to normal operation.

### 13.12.3 Programming debug events

In Halting debug-mode debugging you can program the following debug events:

- *Setting breakpoints, watchpoints, and vector catch debug events* on page 13-48

- *Setting software breakpoints (BKPT)*
- *Reading and writing to memory.*

### Setting breakpoints, watchpoints, and vector catch debug events

For setting breakpoints, watchpoints, and vector catch debug events when in Halting debug-mode, the debug host has to use the same CP14 debug registers and the same sequence of operations as in Monitor debug-mode debugging (see *Setting breakpoints, watchpoints, and vector catch debug events* on page 13-41). The only difference is that the CP14 debug registers are accessed using the DBGTAP scan chains, see *The DBGTAP port and debug registers* on page 14-6.

---

#### Note

A DBGTAP debugger can access the CP14 debug registers whether the processor is in Debug state or not, so these debug events can be programmed when the processor is in ARM state or, Thumb state.

---

### Setting software breakpoints (BKPT)

To set a software breakpoint, the DBGTAP debugger must perform the same steps as the monitor target (described in *Setting breakpoints, watchpoints, and vector catch debug events* on page 13-41). The difference is that CP14 debug registers are accessed using the DBGTAP scan chains, see Chapter 14 *Debug Test Access Port*.

### Reading and writing to memory

See *Debug sequences* on page 14-34 for memory access sequences using the ARM1156T2F-S Debug Test Access Port.

### 13.13 External signals

The following external signals are used by debug:

|                    |                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DBGACK</b>      | Debug acknowledge signal. The processor asserts this output signal to indicate the system has entered Debug state. See <i>Debug state</i> on page 13-35 for a definition of the Debug state.                                                                                                                |
| <b>DBGEN</b>       | Debug enable signal. When this signal is LOW, DSCR[15:14] is read as 0 and the processor behaves as if in debug disabled mode.                                                                                                                                                                              |
| <b>EDBGRQ</b>      | External debug request signal. As described in <i>External debug request signal</i> on page 13-29, this input signal forces the core into Debug state.                                                                                                                                                      |
| <b>DBGNOPWRDWN</b> | Powerdown disable signal generated from DSCR[9]. When this signal is HIGH, the system power controller is forced into Emulate mode. This is to avoid losing CP14 Debug state that can only be written through the DBGTAP. Therefore, DSCR[9] must only be set if Halting debug-mode debugging is necessary. |

# Chapter 14

## Debug Test Access Port

This chapter introduces the Debug Test Access Port built into ARM1156T2F-S processor. It contains the following sections:

- *Debug Test Access Port and Halting debug-mode* on page 14-2
- *Synchronizing RealView™ ICE* on page 14-3
- *Entering Debug state* on page 14-4
- *Exiting Debug state* on page 14-5
- *The DBGTAP port and debug registers* on page 14-6
- *Debug registers* on page 14-8
- *Using the Debug Test Access Port* on page 14-24
- *Debug sequences* on page 14-34
- *Programming debug events* on page 14-48
- *Monitor debug-mode debugging* on page 14-50.

## 14.1 Debug Test Access Port and Halting debug-mode

JTAG-based hardware debug using Halting debug-mode provides access to the ARM1156T2F-S processor and debug unit. Access is through scan chains and the *Debug Test Access Port* (DBGTAP). The *DBGTAP state Machine* (DBGTAPM) is illustrated in Figure 14-1.

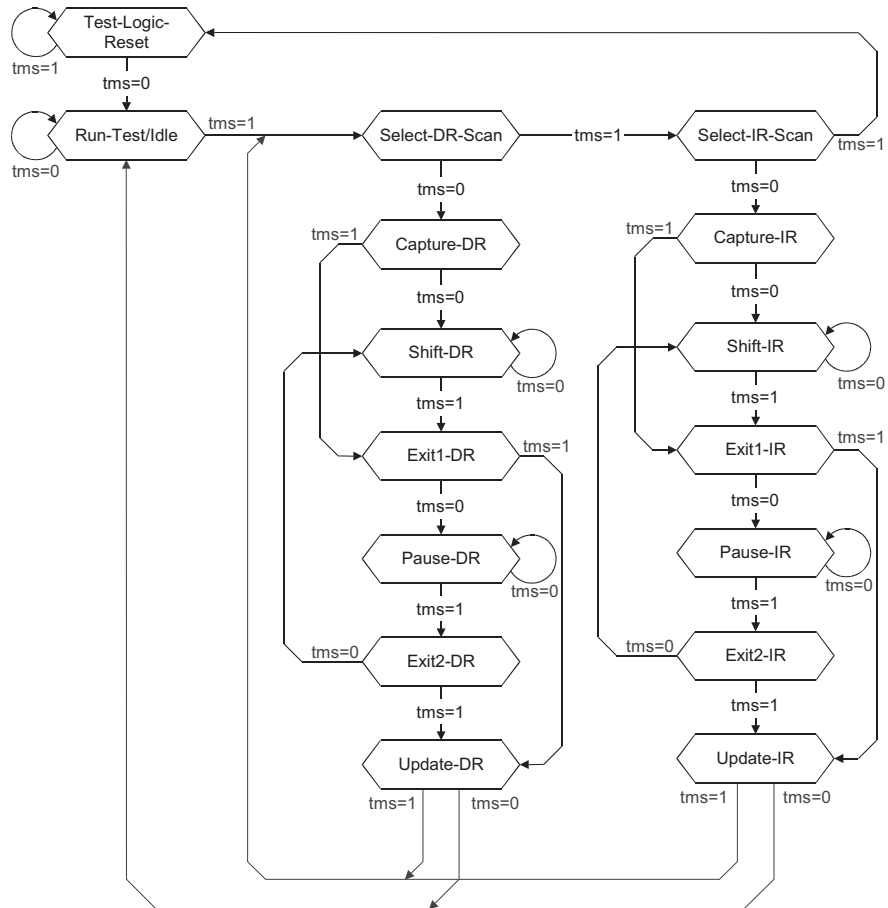

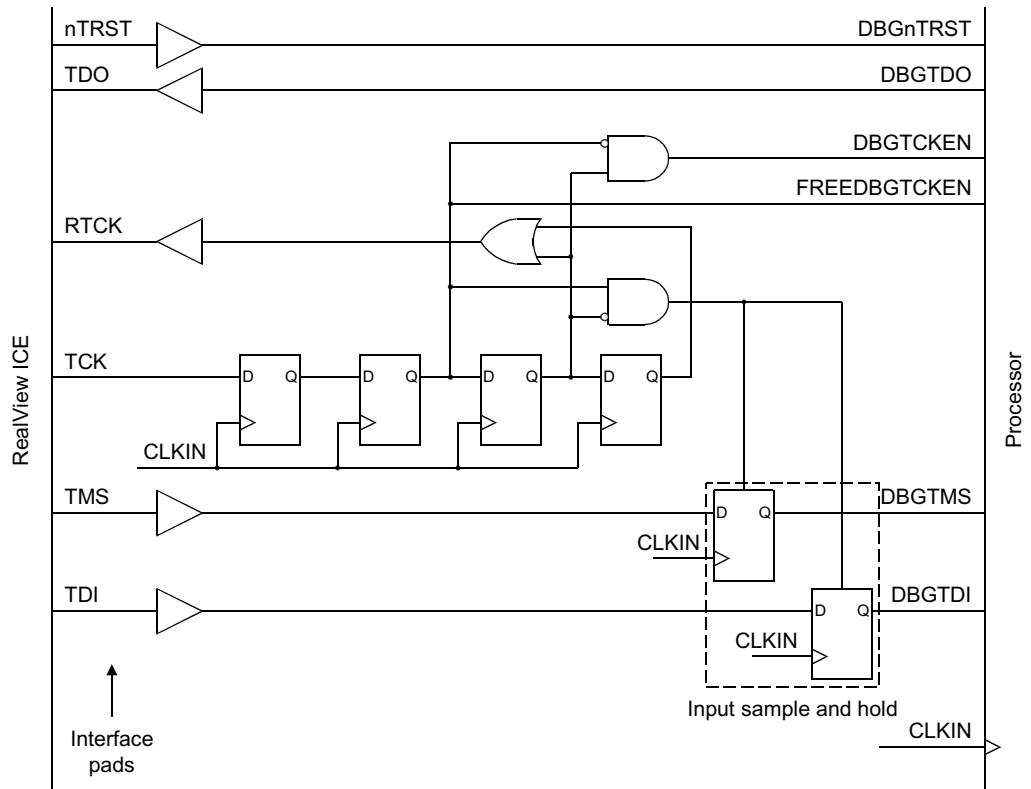

Figure 14-1 JTAG DBGTAP state machine diagram<sup>1</sup>

## 14.2 Synchronizing RealView™ ICE

The system and test clocks must be synchronized externally to the macrocell. The ARM RealView ICE debug agent directly supports one or more cores within an ASIC design. To synchronize off-chip debug clocking with the ARM1156T2F-S processor you must use a three-stage synchronizer. The off-chip device (for example, RealView ICE) issues a **TCK** signal and waits for the **RTCK** (**R**eturned **TCK**) signal to come back. Synchronization is maintained because the off-chip device does not progress to the next **TCK** edge until after an **RTCK** edge is received. Figure 14-2 shows this synchronization.

**Figure 14-2** Clock synchronization

**Note**

All of the D types are reset by **DBGnTRST**.

## 14.3 Entering Debug state

Halting debug-mode is enabled by writing a 1 to bit 14 of the DSCR, see *CP14 c1, Debug Status and Control Register (DSCR)* on page 13-9. This can only be done by a DBGTAP debugger hardware such as RealView ICE. When this mode is enabled the processor halts, instead of taking an exception in software, if one of the following events occurs:

- A vector catch occurs.
- A breakpoint hits.
- A watchpoint hits.
- A BKPT instruction is executed.

The processor halts regardless of the state of bit 14 of the DSCR when:

- A Halt instruction has been scanned in through the DBGTAP. The DBGTAP controller must pass through Run-Test/Idle to issue the Halt command to the ARM.
- **EDBGRQ** is asserted.

The core halted bit in the DSCR is set when Debug state is entered. At this point, the debugger determines why the integer unit was halted and preserves the processor state. The MSR instruction can be used to change modes and gain access to all banked registers in the machine. While in Debug state:

- the PC is not incremented
- interrupts are ignored
- all instructions are read from the Instruction Transfer Register (scan chain 4).

Debug state is described in *Debug state* on page 13-35.

## 14.4 Exiting Debug state

To exit from Debug state, scan in the Restart instruction through the ARM1156T2F-S DBGTAP. You might want to adjust the PC before restarting, depending on the way the integer unit entered Debug state. When the state machine enters the Run-Test/Idle state, normal operations resume. The delay, waiting until the state machine is in Run-Test/Idle, enables conditions to be set up in other devices in a multiprocessor system without taking immediate effect. When Run-Test/Idle state is entered, all the processors resume operation simultaneously. The core restarted bit is set when the Restart sequence is complete.

## 14.5 The DBGTAP port and debug registers

The ARM1156T2F-S DBGTAP controller is the part of the debug unit that enables access through the DBGTAP to the on-chip debug resources, such as breakpoint and watchpoint registers. The DBGTAP controller is based on the IEEE 1149.1 standard and supports:

- a Device ID Register
- a Bypass Register
- a five-bit Instruction Register
- a five-bit Scan Chain Select Register.

In addition, the public instructions listed in Table 14-1 are supported.

Table 14-1 Supported public instructions

| Binary code   | Instruction | Description                                                                                                                                                                                                                                  |
|---------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| b00000        | EXTEST      | This instruction connects the selected scan chain between <b>DBGTDI</b> and <b>DBGTDO</b> . When the instruction register is loaded with the EXTEST instruction, the debug scan chains can be written. See <i>Scan chains</i> on page 14-11. |
| b00001        | -           | Reserved.                                                                                                                                                                                                                                    |
| b00010        | Scan_N      | Selects the <i>Scan Chain Select Register</i> (SCREG). This instruction connects SCREG between <b>DBGTDI</b> and <b>DBGTDO</b> . See <i>Scan Chain Select Register (SCREG)</i> on page 14-10.                                                |
| b00011        | -           | Reserved.                                                                                                                                                                                                                                    |
| b00100        | Restart     | Forces the processor to leave Debug state. This instruction is used to exit from Debug state. The processor restarts when the Run-Test/Idle state is entered.                                                                                |
| b00101        | -           | Reserved.                                                                                                                                                                                                                                    |
| b00110        | -           | Reserved.                                                                                                                                                                                                                                    |
| b00111        | -           | Reserved.                                                                                                                                                                                                                                    |
| b01000        | Halt        | Forces the processor to enter Debug state. This instruction is used to stop the integer unit and put it into Debug state.                                                                                                                    |
| b01001        | -           | Reserved.                                                                                                                                                                                                                                    |
| b01010-b01011 | -           | Reserved.                                                                                                                                                                                                                                    |
| b01100        | INTEST      | This instruction connects the selected scan chain between <b>DBGTDI</b> and <b>DBGTDO</b> . When the instruction register is loaded with the INTEST instruction, the debug scan chains can be read. See <i>Scan chains</i> on page 14-11.    |

Table 14-1 Supported public instructions (continued)

| Binary code   | Instruction | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| b01101-b11100 | -           | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| b11101        | ITRsel      | When this instruction is loaded into the IR (Update-DR state), the DBGTap controller behaves as if IR=EXTEST and SCREG=4. The ITRsel instruction makes the DBGTap controller behave as if EXTEST and scan chain 4 are selected. It can be used to speed up certain debug sequences. See <i>Using the ITRsel IR instruction</i> on page 14-25 for the effects of using this instruction.                                                                                         |
| b11110        | IDcode      | See IEEE 1149.1. Selects the DBGTap controller device ID code register.<br>The IDcode instruction connects the device identification register (or ID register) between <b>DBGTDI</b> and <b>DBGTDO</b> . The ID register is a 32-bit register that enables you to determine the manufacturer, part number, and version of a component using the DBGTap.<br><br>See <i>Device ID Code Register</i> on page 14-9 for details of selecting and interpreting the ID register value. |
| b11111        | Bypass      | See IEEE 1149.1. Selects the DBGTap controller bypass register. The Bypass instruction connects a 1-bit shift register (the bypass register) between <b>DBGTDI</b> and <b>DBGTDO</b> . The first bit shifted out is a 0. All unused DBGTap controller instruction codes default to the Bypass instruction. See <i>Bypass Register</i> on page 14-8.                                                                                                                             |

---

**Note**

---

- Sample/Preload, Clamp, HighZ, and ClampZ instructions are not implemented because the ARM1156T2F-S DBGTap controller does not support the attachment of external boundary scan chains.
  - All unused DBGTap controller instructions default to the Bypass instruction.
-

## 14.6 Debug registers

You can connect the following debug registers between **DBGTDI** and **DBGTDO**:

- *Bypass Register*
- *Device ID Code Register* on page 14-9
- *Instruction Register* on page 14-9
- *Scan Chain Select Register (SCREG)* on page 14-10
- *Scan chain 0, Debug Id Register (DIDR)* on page 14-12
- *Scan chain 1, Debug Status And Control Register (DSCR)* on page 14-12
- *Scan chain 4, Instruction Transfer Register (ITR)* on page 14-14
- *Scan chain 5* on page 14-16.
- *Scan chain 6* on page 14-19.
- *Scan chain 7* on page 14-19.

### 14.6.1 Bypass Register

|                |                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose        | Bypasses the device by providing a path between <b>DBGTDI</b> and <b>DBGTDO</b> .                                                                                                                                                                                                                                                                                                                        |
| Length         | 1 bit.                                                                                                                                                                                                                                                                                                                                                                                                   |
| Operating mode | When the bypass instruction is the current instruction in the instruction register, serial data is transferred from <b>DBGTDI</b> to <b>DBGTDO</b> in the Shift-DR state with a delay of one <b>TCK</b> cycle. There is no parallel output from the bypass register. A logic 0 is loaded from the parallel input of the bypass register in the Capture-DR state. Nothing happens at the Update-DR state. |
| Order          | Figure 14-3 shows the order of bits in the bypass register.                                                                                                                                                                                                                                                                                                                                              |

**Figure 14-3 Bypass register bit order**

## 14.6.2 Device ID Code Register

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>        | Device identification. To distinguish the ARM1156T2F-S processor from other processors, the DBGTAP controller ID is unique for each. This means that a DBGTAP debugger such as RealView ICE can easily see which processor it is connected to. The Device ID register version and manufacturer ID fields are routed to the edge of the chip so that partners can create their own Device ID numbers by tying the pins to HIGH or LOW values. The default manufacturer ID for the ARM1156T2F-S processor is b11110000111. The part number field is hard-wired inside the ARM1156T2F-S to 0x7B56. All ARM semiconductor partner-specific devices must be identified by manufacturer ID numbers of the form shown in <i>c0, Main ID Register</i> on page 3-18. |
| <b>Length</b>         | 32 bits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Operating mode</b> | When the ID code instruction is current, the shift section of the device ID register is selected as the serial path between <b>DBGTDI</b> and <b>DBGTDO</b> . There is no parallel output from the ID register. The 32-bit device ID code is loaded into this shift section during the Capture-DR state. This is shifted out during Shift-DR (least significant bit first) while a <i>don't care</i> value is shifted in. The shifted-in data is ignored in the Update-DR state.                                                                                                                                                                                                                                                                            |
| <b>Order</b>          | The order of bits in the ID code register is shown in Figure 14-4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Figure 14-4 Device ID code register bit order**

## 14.6.3 Instruction Register

|                |                                                  |
|----------------|--------------------------------------------------|
| <b>Purpose</b> | Holds the current DBGTAP controller instruction. |
| <b>Length</b>  | 5 bits.                                          |

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Operating mode</b> | When in Shift-IR state, the shift section of the instruction register is selected as the serial path between <b>DBGTDI</b> and <b>DBGTDO</b> . At the Capture-IR state, the binary value b00001 is loaded into this shift section. This is shifted out during Shift-IR (least significant bit first), while a new instruction is shifted in (least significant bit first). At the Update-IR state, the value in the shift section is loaded into the instruction register so it becomes the current instruction. On DBGTAP reset, the IDcode becomes the current instruction. |
| <b>Order</b>          | The order of bits in the instruction register is shown in Figure 14-5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Figure 14-5 Instruction register bit order

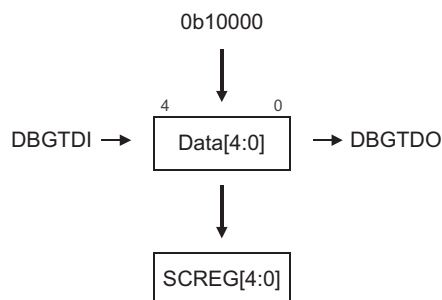

14.6.4 Scan Chain Select Register (SCREG)

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>        | Holds the currently active scan chain number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Length</b>         | 5 bits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Operating mode</b> | After Scan_N has been selected as the current instruction, when in Shift-DR state, the shift section of the scan chain select register is selected as the serial path between <b>DBGTDI</b> and <b>DBGTDO</b> . At the Capture-DR state, the binary value b10000 is loaded into this shift section. This is shifted out during Shift-DR (least significant bit first), while a new value is shifted in (least significant bit first). At the Update-DR state, the value in the shift section is loaded into the Scan Chain Select Register to become the current active scan chain. All subsequent instructions such as INTEST then apply to that scan chain. The currently selected scan chain only changes when a Scan_N or ITRsel instruction is executed, or a DBGTAP reset occurs. On DBGTAP reset, scan chain 3 is selected as the active scan chain. |

**Order**

The order of bits in the scan chain select register is shown in Figure 14-6.

**Figure 14-6 Scan chain select register bit order**

### 14.6.5 Scan chains

To access the debug scan chains you must:

1. Load the Scan\_N instruction into the IR. Now SCREG is selected between **DBGTDI** and **DBGTDO**.
2. Load the number of the desired scan chain. For example, load b00101 to access scan chain 5.
3. Load either INTEST or EXTEST into the IR.
4. Go through the DR leg of the DBGTAPSM to access the scan chain.

INTEST and EXTEST are used as follows:

**INTEST** Use INTEST for reading the active scan chain. Data is captured into the shift register at the Capture-DR state. The previous value of the scan chain is shifted out during the Shift-DR state, while a new value is shifted in. The scan chain is not updated during Update-DR. Those bits or fields that are defined as cleared on read are only cleared if INTEST is selected, even when EXTEST also captures their values.

**EXTEST** Use EXTEST for writing the active scan chain. Data is captured into the shift register at the Capture-DR state. The previous value of the scan chain is shifted out during the Shift-DR state, while a new value is shifted in. The scan chain is updated with the new value during Update-DR.

**Note**

There are some exceptions to this use of INTEST and EXTEST to control reading and writing the scan chain. These are noted in the relevant scan chain descriptions.

**Scan chain 0, Debug Id Register (DIDR)**

- Purpose** Debug.
- Length** 8 + 32 = 40 bits.
- Description** Debug identification. This scan chain accesses CP14 debug register 0, the debug ID register. Additionally, the eight most significant bits of this scan chain contain an implementer code. This field is hardwired to 0x41, the implementer code for ARM Limited, as specified in the *ARM Architecture Reference Manual*. This register is read-only. Therefore, EXTEST has the same effect as INTEST.
- Order** The order of bits in scan chain 0 is shown in Figure 14-7.

Figure 14-7 Scan chain 0 bit order

**Scan chain 1, Debug Status And Control Register (DSCR)**

- Purpose** Debug.
- Length** 32 bits.
- Description** This scan chain accesses CP14 register 1, the DSCR. This is mostly a read/write register, although certain bits are read-only for the Debug Test Access Port. See *CP14 c1, Debug Status and Control Register (DSCR)* on page 13-9 for details of DSCR bit definitions, and for read/write attributes for each bit. Those bits defined as cleared on read are only cleared if INTEST is selected.
- Order** The order of bits in scan chain 1 is shown in Figure 14-8 on page 14-13.

**Figure 14-8 Scan chain 1 bit order**

The following DSCR bits affect the operation of other scan chains:

- DSCR[30:29]** rDTRfull and wDTRfull flags. These indicate the status of the rDTR and wDTR registers. They are copies of the rDTRempty (NOT rDTRfull) and wDTRfull bits that the DBGTap debugger sees in scan chain 5.
- DSCR[13]** Execute ARM instruction enable bit. This bit enables the mechanism used for executing instructions in Debug state. It changes the behavior of the rDTR and wDTR registers, the sticky precise Data Abort bit, rDTRempty, wDTRfull, and InstCompl flags. See *Scan chain 5* on page 14-16.
- DSCR[6]** Sticky precise Data Abort flag. If the core is in Debug state and the DSCR[13] execute ARM instruction enable bit is HIGH, then this flag is set on precise Data Aborts. See *CP14 c1, Debug Status and Control Register (DSCR)* on page 13-9.

**Note**

Unlike DSCR[6], DSCR [7] sticky imprecise Data Aborts flag does not affect the operation of the other scan chains.

**Scan chain 4, Instruction Transfer Register (ITR)****Purpose** Debug.**Length** 1 + 32 = 33 bits.**Description** This scan chain accesses the *Instruction Transfer Register (ITR)*, used to send instructions to the core through the *PreFetch Unit (PFU)*. It consists of 32 bits of information, plus an additional bit to indicate the completion of the instruction sent to the core (InstCompl). The InstCompl bit is read-only.

While in Debug state, an instruction loaded into the ITR can be issued to the core by making the DBGTAPSM go through the Run-Test/Idle state. The InstCompl flag is cleared when the instruction is issued to the core and set when the instruction completes.

For an instruction to be issued when going through Run-Test/Idle state, you must ensure the following conditions are met:

- The processor must be in Debug state.
- The DSCR[13] execute ARM instruction enable bit must be set. For details of the DSCR, see *CP14 c1, Debug Status and Control Register (DSCR)* on page 13-9.
- Scan chain 4 or 5 must be selected.
- INTEST or EXTEST must be selected.
- Ready flag must be captured set. That is, the last time the DBGTAPSM went through Capture-DR the InstCompl flag must have been set.
- The DSCR[6] sticky precise Data Abort flag must be clear. This flag is set on precise Data Aborts.

For an instruction to be loaded into the ITR when going through Update-DR, you must ensure the following conditions are met:

- The processor can be in any state.
- The value of DSCR[13] execute ARM instruction enable bit does not matter.
- Scan chain 4 must be selected.
- EXTEST must be selected.
- Ready flag must be captured set. That is, the last time the DBGTAPSM went through Capture-DR the InstCompl flag must have been set.

- The value of DSCR[6] sticky precise Data Abort flag does not matter.

**Order** The order of bits in scan chain 4 is shown in Figure 14-9.

**Figure 14-9 Scan chain 4 bit order**

It is important to distinguish between the InstCompl flag and the Ready flag:

- The InstCompl flag signals the completion of an instruction.
- The Ready flag is the captured version of the InstCompl flag, captured at the Capture-DR state. The Ready flag conditions the execution of instructions and the update of the ITR.

The following points apply to the use of scan chain 4:

- When an instruction is issued to the core in Debug state, the PC is not incremented. It is only changed if the instruction being executed explicitly writes to the PC. For example, branch instructions and move to PC instructions.
- If CP14 debug register c5 is a source register for the instruction to be executed, the DBG TAP debugger must set up the data in the rDTR before issuing the coprocessor instruction to the core. See *Scan chain 5* on page 14-16.
- Setting DSCR[13] the execute ARM instruction enable bit when the core is not in Debug state leads to Unpredictable behavior.
- The ITR is write-only. When going through the Capture-DR state, an Unpredictable value is loaded into the shift register.

Scan chain 5

- Purpose

Debug.
- Length

1 + 1 + 32 = 34 bits.
- Description

This scan chain accesses CP14 register c5, the data transfer registers, rDTR and wDTR. The rDTR is used to transfer words from the DBGTAP debugger to the core, and is read-only to the core and write-only to the DBGTAP debugger. The wDTR is used to transfer words from the core to the DBGTAP debugger, and is read-only to the DBGTAP debugger and write-only to the core.

The DBGTAP controller only sees one (read/write) register through scan chain 5, and the appropriate register is chosen depending on the instruction used. INTEST selects the wDTR, and EXTEST selects the rDTR.

Additionally, scan chain 5 contains some status flags. These are nRetry, Valid, and Ready, which are the captured versions of the rDTRempty, wDTRfull, and InstCompl flags respectively. All are captured at the Capture-DR state.
- Order

The order of bits in scan chain 5 with EXTEST selected is shown in Figure 14-10. The order of bits in scan chain 5 with INTEST selected is shown in Figure 14-11 on page 14-17.

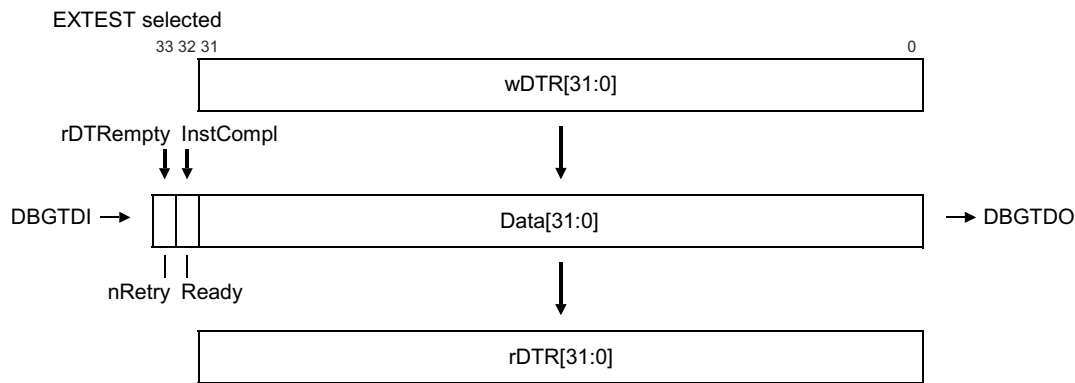

Figure 14-10 Scan chain 5 bit order, EXTEST selected

**Figure 14-11 Scan chain 5 bit order, INTEST selected**

You can use scan chain 5 for two purposes:

- As part of the *Debug Communications Channel* (DCC). The DBGTap debugger uses scan chain 5 to exchange data with software running on the core. The software accesses the rDTR and wDTR using coprocessor instructions.
- For examining and modifying the processor state while the core is halted. For example, to read the value of an ARM register:
  1. Issue a MCR cp14, 0, Rd, c0, c5, 0 instruction to the core to transfer the register contents to the CP14 debug c5 register.
  2. Scan out the wDTR.

The DBGTap debugger can use the DSCR[13] execute ARM instruction enable bit to indicate to the core that it is going to use scan chain 5 as part of the DCC or for examining and modifying the processor state. DSCR[13] = 0 indicates DCC use. The behavior of the rDTR and wDTR registers, the sticky precise Data Abort, rDTRempty, wDTRfull, and InstCompl flags changes accordingly:

- DSCR[13] = 0:
  - The wDTRfull flag is set when the core writes a word of data to the DTR and cleared when the DBGTap debugger goes through the Capture-DR state with INTEST selected. Valid indicates the state of the wDTR register, and is the captured version of wDTRfull. Although the value of wDTR is captured into the shift register, regardless of INTEST or EXTEST, wDTRfull is only cleared if INTEST is selected.
  - The rDTR empty flag is cleared when the DBGTap debugger writes a word of data to the rDTR, and set when the core reads it. nRetry is the captured version of rDTRempty.

- rDTR overwrite protection is controlled by the nRetry flag. If the nRetry flag is sampled clear, meaning that the rDTR is full, when going through the Capture-DR state, then the rDTR is not updated at the Update-DR state.
- The InstCompl flag is always set.
- The sticky precise Data Abort flag is Unpredictable. See *CP14 c1, Debug Status and Control Register (DSCR)* on page 13-9.
- DSCR[13] = 1:
  - The wDTR Full flag behaves as if DSCR[13] is clear. However, the Ready flag can be used for handshaking in this mode.
  - The rDTR Empty flag status behaves as if DSCR[13] is clear. However, the Ready flag can be used for handshaking in this mode.
  - rDTR overwrite protection is controlled by the Ready flag. If the InstCompl flag is sampled clear when going through Capture-DR, then the rDTR is not updated at the Update-DR state. This prevents an instruction that uses the rDTR as a source operand from having it modified before it has time to complete.
  - The InstCompl flag changes from 1 to 0 when an instruction is issued to the core, and from 0 to 1 when the instruction completes execution.
  - The sticky precise Data Abort flag is set on precise Data Aborts.

The behavior of the rDTR and wDTR registers, the sticky precise Data Abort, rDTRempty, wDTRfull, and InstCompl flags when the core changes state is as follows:

- The DSCR[13] execute ARM instruction enable bit must be clear when the core is not in Debug state. Otherwise, the behavior of the rDTR and wDTR registers, and the flags, is Unpredictable.
- When the core enters Debug state, none of the registers and flags are altered.
- When the DSCR[13] execute ARM instruction enable bit is changed from 0 to 1:
  1. None of the registers and flags are altered.
  2. Ready flag can be used for handshaking.
- The InstCompl flag must be set when the DSCR[13] execute ARM instruction enable bit is changed from 1 to 0. Otherwise, the behavior of the core is Unpredictable. If the DSCR[13] flag is cleared correctly, none of the registers and flags are altered.
- When the core leaves Debug state, none of the registers and flags are altered.

## Scan chain 6

**Purpose** Embedded Trace Macrocell.

**Length**  $1 + 7 + 32 = 40$  bits.

**Description** This scan chain accesses the register map of the Embedded Trace Macrocell. See the description in the programmer's model chapter in the *Embedded Trace Macrocell Architecture Specification* for details of register allocation.

To access this scan chain, you must select INTEST. Accesses to scan chain 6 with EXTEST selected are ignored. Bit 39, the nRW bit, is used to distinguish between reads and writes, as described in the Embedded Trace Macrocell Architecture Specification.

### Note

For scan chain 6, the use of INTEST and EXTEST differs from their standard use described at the start of this section.

**Order** The order of bits in scan chain 6 is shown in Figure 14-12.

**Figure 14-12 Scan chain 6 bit order**

## Scan chain 7

**Purpose** Debug.

**Length**  $7 + 32 + 1 = 40$  bits.

**Description** Scan chain 7 accesses the VCR, PC, BRPs, and WRPs. The accesses are performed with the help of read or write request commands. A read request copies the data held by the addressed register into scan chain 7. A write request copies the data held by the scan chain into the addressed register. When a request is finished the ReqCompl flag is set. The DBGTap debugger must poll it and check it is set before another request can be issued. The exact behavior of the scan chain is as follows:

- Either EXTEST or INTEST must be selected. EXTEST or INTEST the same meaning in this scan chain.

---

**Note**

---

For scan chain 7, the use of INTEST and EXTEST differs from the standard use described at the start of this section.

---

- If the value captured by the Ready/nRW bit at the Capture-DR state is 1, the data that is being shifted in generates a request at the Update-DR state. The Address field indicates the register being accessed (see Table 14-2 on page 14-22), the Data field contains the data to be written and the Ready/nRW bit holds the read/write information (0=read and 1=write). If the request is a read, the Data field is ignored.
- When a request is placed, the Address and Data sections of the scan chain are frozen. That is, their contents are not shifted until the request is completed. This means that, if the value captured in the Ready/nRW field at the Capture-DR state is 0, the shifted-in data is ignored and the shifted-out value is all 0s.
- After a read request has been placed, if the DBGTAPEM goes through the Capture-DR state and a logic 1 is captured in the Ready/nRW field, this means that the shift register has also captured the requested register contents. Therefore, they are shifted out at the same time as the Ready/nRW bit. The Data field is corrupted as new data is shifted in.
- After a write request has been placed, if the DBGTAPEM goes through the Capture-DR state and a logic 1 is captured in the Ready/nRW field, this means that the requested write has completed successfully.
- If the Address field is all 0s (address of the NULL register) at the Update-DR state, then no request is generated.
- A request to a reserved register generates Unpredictable behavior.

**Order** The order of bits in scan chain 7 is shown in Figure 14-13 on page 14-21.

**Figure 14-13 Scan chain 7 bit order**

A typical sequence for writing registers is as follows:

1. Scan in the address of a first register, the data to write, and a 1 to indicate that this is a write request.  
Scan out 40 bits. If Ready/nRW is 0 repeat this step. If Ready/nRW is 1, the first write request has completed successfully and the second has been placed.
2. Scan in the address of a second register, the data to write, and a 1 to indicate that this is a write request.  
Scan out 40 bits. If Ready/nRW is 0 repeat this step. If Ready/nRW is 1, the second write request has completed successfully. The scanned-in null request has avoided the generation of another request.
3. Scan in the address 0. The rest of the fields are not important.  
Scan out 40 bits. If Ready/nRW is 0 repeat this step. If Ready/nRW is 1, the second write request has completed successfully. The scanned-in null request has avoided the generation of another request.

A typical sequence for reading registers is as follows:

1. Scan in the address of a first register and a 0 to indicate that this is a read request. The Data field is not important.  
Scan out 40 bits. If Ready/nRW is 0 then repeat this step. If Ready/nRW is 1, the first read request has completed successfully and the next scanned-out 32 bits are the requested value. The second read request was placed at the Update-DR state.
2. Scan in the address of a second register and a 0 to indicate that this is a read request.  
Scan out 40 bits. If Ready/nRW is 0 then repeat this step. If Ready/nRW is 1, the first read request has completed successfully and the next scanned-out 32 bits are the requested value. The scanned-in null request has avoided the generation of another request.
3. Scan in the address 0 (the rest of the fields are not important).  
Scan out 40 bits. If Ready/nRW is 0 then repeat this step. If Ready/nRW is 1, the second read request has completed successfully and the next scanned-out 32 bits are the requested value. The scanned-in null request has avoided the generation of another request.

The register map is similar to the one of CP14 debug, and is shown in Table 14-2.

**Table 14-2 Scan chain 7 register map**

| Address[6:0]      | Register number | Abbreviation                  | Register name                |
|-------------------|-----------------|-------------------------------|------------------------------|
| b0000000          | 0               | NULL                          | No request register          |
| b0000001-b0000110 | 1-6             | -                             | Reserved                     |
| b0000111          | 7               | VCR                           | Vector catch register        |
| b0001000          | 8               | PC                            | Program counter              |
| b0010011-b0111111 | 19-63           | -                             | Reserved                     |
| b1000000-b1000101 | 64-69           | BVR <sub>y</sub> <sup>a</sup> | Breakpoint value registers   |
| b1000110-b1001111 | 70-79           | -                             | Reserved                     |
| b1010000-b1010101 | 80-85           | BCR <sub>y</sub> <sup>a</sup> | Breakpoint Control Registers |
| b1010110-b1011111 | 86-95           | -                             | Reserved                     |
| b1100000-b1100001 | 96-97           | WVR <sub>y</sub> <sup>a</sup> | Watchpoint Value Registers   |
| b1100010-b1101111 | 98-111          | -                             | Reserved                     |
| b1110000-b1110001 | 112-113         | WCR <sub>y</sub> <sup>a</sup> | Watchpoint Control Registers |
| b1110010-b1111111 | 114-127         | -                             | Reserved                     |

a. <sub>y</sub> is the decimal representation for the binary number Address[3:0]

The following points apply to the use of scan chain 7:

- Every time there is a request to read the PC, a sample of its value is copied into scan chain 7. Writes are ignored. The sampled value can be used for profiling of the code. See *Interpreting the PC samples* on page 14-23 for details of how to interpret the sampled value.
- The external program counter sample register always reads 0xFFFFFFFF in Debug state or when the core is in a mode when Non-invasive debug is not permitted.
- When accessing registers using scan chain 7, the processor can be either in Debug state or in normal state. This implies that breakpoints, watchpoints, and vector catches can be programmed through the Debug Test Access Port even if the processor is running.

## Interpreting the PC samples

The PC values read correspond to instructions committed for execution, including those that failed their condition code. However, these values are offset as described in Table 13-14 on page 13-30. These offsets are different for different processor states, so additional information is required:

- If a read request to the PC completes and Data[1:0] equals b00, the read value corresponds to an ARM state instruction whose 30 most significant bits of the offset address (instruction address + 8) are given in Data[31:2].
- If a read request to the PC completes and Data[0] equals b1, the read value corresponds to a Thumb state instruction whose 31 most significant bits of the offset address (instruction address + 4) are given in Data[31:1].
- If the PC is read while the processor is in Debug state, the result is 0xFFFFFFFF.

## Scan chains 8-15

These scan chains are reserved.

## Scan chains 16-31

These scan chains are unassigned.

## 14.6.6 Reset

The DBGTap is reset either by asserting **DBGnTRST**, or by clocking it while DBGTapSM is in the Test-Logic-Reset state. The processor, including CP14 debug logic, is not affected by these events. See *Reset modes* on page 9-4 and *CP14 registers reset* on page 13-24 for details.

## 14.7 Using the Debug Test Access Port

This section contains the following subsections:

- *Entering and leaving Debug state*
- *Executing instructions in Debug state*
- *Using the ITRsel IR instruction on page 14-25*
- *Transferring data between the host and the core on page 14-27*
- *Using the debug communications channel on page 14-27*
- *Target to host debug communications channel sequence on page 14-28*
- *Host to target debug communications channel on page 14-29*
- *Transferring data in Debug state on page 14-29*
- *Example sequences on page 14-30.*

### 14.7.1 Entering and leaving Debug state

These debug sequences are described in detail in *Debug sequences* on page 14-34.

### 14.7.2 Executing instructions in Debug state

When the processor is in Debug state, it can be forced to execute ARM state instructions using the DBGTap. Two registers are used for this purpose, the *Instruction Transfer Register* (ITR) and the *Data Transfer Register* (DTR). The ITR is used to insert an instruction into the processor pipeline. An ARM state instruction can be loaded into this register using scan chain number 4. When the instruction is loaded, and INTEST or EXTEST is selected, and scan chain 4 or 5 is selected, the instruction can be issued to the core by making the DBGTapSM go through the Run-Test/Idle state, provided certain conditions are met (described in this section). This mechanism enables re-executing the same instruction over and over without having to reload it. The DTR can be used in conjunction with the ITR to transfer data in and out of the core. For example, to read out the value of an ARM register:

1. Issue an MCR p14, 0, Rd, c5, 0 instruction to the core to transfer the <Rd> contents to the c5 register.
2. Scan out the wDTR.

The DSCR[13] execute ARM instruction enable bit controls the activation of the ARM instruction execution mechanism. If this bit is cleared, no instruction is issued to the core when the DBGTapSM goes through Run-Test/Idle. Setting this bit while the core is not in Debug state leads to Unpredictable behavior. If the core is in Debug state and this bit is set, the Ready and the sticky precise Data Abort flags condition the updates

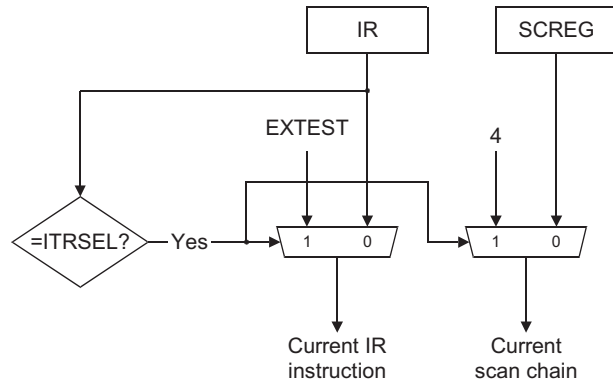

of the ITR and the instruction issuing as described in *Scan chain 4, Instruction Transfer Register (ITR)* on page 14-14. As an example, this sequence stores out the contents of the ARM register r0:

1. Scan\_N into the IR.
2. 1 into the SCREG.
3. INTEST into the IR.
4. Scan out the contents of the DSCR. This action clears the sticky precise Data Abort and sticky imprecise Data Abort flags.
5. EXTEST into the IR.
6. Scan in the previously read value with the DSCR[13] execute ARM instruction enable bit set.
7. Scan\_N into the IR.
8. 4 into the SCREG.
9. EXTEST into the IR.
10. Scan the MCR p14, 0, R0, c0, c5, 0 instruction into the ITR.
11. Go through the Run-Test/Idle state of the DBGTAPSM.
12. Scan\_N into the IR.
13. 5 into the SCREG.
14. INTEST into the IR.
15. Scan out 34 bits. The 33rd bit indicates if the instruction has completed. If the bit is clear, repeat this step again.
16. The least significant 32 bits hold the contents of r0.

### 14.7.3 Using the ITRsel IR instruction

When the ITRsel instruction is loaded into the IR, at the Update-IR state, the DBGTAP controller behaves as if EXTEST and scan chain 4 are selected, but SCREG retains its value. It can be used to speed up certain debug sequences.

Figure 14-14 on page 14-26 shows the effect of the ITRsel IR instruction.

**Figure 14-14 Behavior of the ITRsel IR instruction**

Consider for example the preceding sequence to store out the contents of ARM register r0. This is the same sequence using the ITRsel instruction:

1. Scan\_N into the IR.
2. 1 into the SCREG.
3. INTEST into the IR.
4. Scan out the contents of the DSCR. This action clears the sticky precise Data Abort and sticky imprecise Data Abort flags.
5. EXTEST into the IR.
6. Scan in the previously read value with the DSCR[13] execute ARM instruction enable bit set.
7. Scan\_N into the IR.
8. 5 into the SCREG.
9. ITRsel into the IR. Now the DBGTAP controller works as if EXTEST and scan chain 4 is selected.
10. Scan the MCR p14, 0, R0, c0, c5, 0 instruction into the ITR.
11. Go through the Run-Test/Idle state of the DBGTAPSM.
12. INTEST into the IR. Now INTEST and scan chain 5 are selected.
13. Scan out 34 bits. The 33rd bit indicates if the instruction has completed. If the bit is clear, repeat this step again.

14. The least significant 32 bits hold the contents of r0.

The number of steps has been reduced from 16 to 14. However, the bigger reduction comes when reading additional registers. Using the ITRsel instruction there are 6 extra steps (9 to 14), compared with 10 extra steps (7 to 16) in the first sequence.

#### 14.7.4 Transferring data between the host and the core

There are two ways in which a DBGTAP debugger can send or receive data from the core:

- using the DCC, when the ARM1156T2F-S processor is not in Debug state
- using the instruction execution mechanism described in *Executing instructions in Debug state* on page 14-24, when the core is in Debug state.

This is described in:

- *Using the debug communications channel.*
- *Target to host debug communications channel sequence* on page 14-28
- *Host to target debug communications channel* on page 14-29
- *Transferring data in Debug state* on page 14-29
- *Example sequences* on page 14-30.

#### 14.7.5 Using the debug communications channel

The DCC is defined as the set of resources that the external DBGTAP debugger uses to communicate with a piece of software running on the core.

The DCC in the ARM1156T2F-S processor is implemented using the two physically separate DTRs and a full/empty bit pair to augment each register, creating a bidirectional data port. One register can be read from the DBGTAP and is written from the processor. The other register is written from the DBGTAP and read by the processor. The full/empty bit pair for each register is automatically updated by the debug unit hardware, and is accessible to both the DBGTAP and to software running on the processor.

At the core side, the DCC resources are the following:

- CP14 debug register c5 (DTR). Data coming from a DBGTAP debugger can be read by an MRC or STC instruction addressed to this register. The core can write to this register any data intended for the DBGTAP debugger, using an MCR or LDC instruction. Because the DTR comprises both a read (rDTR) and a write portion (wDTR), a piece of data written by the core and another coming from the DBGTAP debugger can be held in this register at the same time.

- Some flags and control bits at CP14 debug register c1 (DSCR):
 

|                 |                                                                                                                                             |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DSCR[12]</b> | User mode access to DCC disable bit. If this bit is set, only privileged software can access the DCC. That is, access the DSCR and the DTR. |
| <b>DSCR[29]</b> | The wDTRfull flag. When clear, this flag indicates to the core that the wDTR is ready to receive data from the core.                        |
| <b>DSCR[30]</b> | The rDTRfull flag. When set, this flag indicates to the core that there is data available to read at the DTR.                               |

At the DBGTAP side, the resources are the following:

- Scan chain 5 (see *Scan chain 5* on page 14-16). The only part of this scan chain that it is not used for the DCC is the Ready flag. The rest of the scan chain is to be used in the following way:
 

|                    |                                                                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>rDTR</b>        | When the DBGTAPSM goes through the Update-DR state with EXTEST and scan chain 5 selected, and the nRetry flag set, the contents of the Data field are loaded into the rDTR. This is how the DBGTAP debugger sends data to the software running on the core.    |
| <b>wDTR</b>        | When the DBGTAPSM goes through the Capture-DR state with INTEST and scan chain 5 selected, the contents of the wDTR are loaded into the Data field of the scan chain. This is how the DBGTAP debugger reads the data sent by the software running on the core. |
| <b>Valid flag</b>  | When set, this flag indicates to the DBGTAP debugger that the contents of the wDTR that it has captured are valid.                                                                                                                                             |
| <b>nRetry flag</b> | When set, this flag indicates to the DBGTAP debugger that the scanned-in Data field has been successfully written into the rDTR at the Update-DR state.                                                                                                        |

#### 14.7.6 Target to host debug communications channel sequence

The DBGTAP debugger can use the following sequence for receiving data from the core:

1. Scan\_N into the IR.
2. 5 into the SCREG.
3. INTEST into the IR.
4. Scan out 34 bits of data. If the Valid flag is clear repeat this step again.

5. The least significant 32 bits hold valid data.
6. Go to step 4 again for reading out more data.

### 14.7.7 Host to target debug communications channel

The DBGTAP debugger can use the following sequence for sending data to the core:

1. Scan\_N into the IR.
2. 5 into the SCREG.
3. EXTEST into the IR.
4. Scan in 34 bits, the least significant 32 holding the word to be sent. At the same time, 34 bits were scanned out. If the nRetry flag is clear repeat this step again.
5. Now the data has been written into the rDTR. Go to step 4 again for sending in more data.

### 14.7.8 Transferring data in Debug state

When the core is in Debug state, the DBGTAP debugger can transfer data in and out of the core using the instruction execution facilities described in *Executing instructions in Debug state* on page 14-24 in addition to scan chain 5. You must ensure that the DSCR[13] execute ARM instruction enable bit is set for the instruction execution mechanism to work. When it is set, the interface for the DBGTAP debugger consists of the following:

- Scan chain 4 (see *Scan chain 4, Instruction Transfer Register (ITR)* on page 14-14). It is used for loading an instruction and for monitoring the status of the execution:

#### **ITR**

When the DBGTAPSM goes through the Update-DR state with EXTEST and scan chain 4 selected, and the Ready flag set, the ITR is loaded with the least significant 32 bits of the scan chain.

#### **InstCompl flag**

When clear, this flag indicates to the DBGTAP debugger that the last issued instruction has not yet completed execution. While Ready (captured version of InstCompl) is clear, no updates of the ITR and the rDTR occur and the instruction execution mechanism is disabled. No instruction is issued when going through Run-Test/Idle.

- Scan chain 5 (see *Scan chain 5* on page 14-16). It is used for writing in or reading out the data and for monitoring the state of the execution:

**rDTR** When the DBGTAPSM goes through the Update-DR state with EXTEST and scan chain 5 selected, and the Ready flag set, the contents of the Data field are loaded into the rDTR.

**wDTR** When the DBGTAPSM goes through the Capture-DR state with INTEST or EXTEST selected, the contents of the wDTR are loaded into the Data field of the scan chain.

**InstCompl flag** When clear, this flag indicates to the DBGTAP debugger that the last issued instruction has not yet completed execution. While Ready (captured version of InstCompl) is clear, no updates of the ITR and the rDTR occur and the instruction execution mechanism is disabled. No instruction is issued when going through Run-Test/Idle.

- Some flags and control bits at CP14 debug register c1 (DSCR):

**DSCR[13]** Execute ARM instruction enable bit. This bit must be set for the instruction execution mechanism to work.

**Sticky precise Data Abort flag**

DSCR[6]. When set, this flag indicates to the DBGTAP debugger that a precise Data Abort occurred while executing an instruction in Debug state. While this bit is set, the instruction execution mechanism is disabled. When this flag is set InstCompl stays HIGH, and additional attempts to execute an instruction appear to succeed but do not execute.

**Sticky imprecise Data Abort flag**

DSCR[7]. When set, this flag indicates to the DBGTAP debugger that an imprecise Data Abort occurred while executing an instruction in Debug state. This flag does not disable the Debug state instruction execution.

## 14.7.9 Example sequences

This section includes some example sequences to illustrate how to transfer data between the DBGTAP debugger and the core when it is in Debug state. The examples are related to accessing the processor memory.

## Target to host transfer

The DBGTAP debugger can use the following sequence for reading data from the processor memory system. The sequence assumes that the ARM register r0 contains a pointer to the address of memory at which the read has to start:

1. Scan\_N into the IR.
2. 1 into the SCREG.
3. INTEST into the IR.
4. Scan out the contents of the DSCR. This clears the sticky precise Data Abort and sticky imprecise Data Abort flags.
5. Scan\_N into the IR.
6. 4 into the SCREG.
7. EXTEST into the IR.
8. Scan in the LDC p14, c5, [R0], #4 instruction into the ITR.
9. Scan\_N into the IR.
10. 5 into the SCREG.
11. INTEST into the IR.
12. Go through Run-Test/Idle state. The instruction loaded into the ITR is issued to the processor pipeline.
13. Scan out 34 bits of data. If the Ready flag is clear repeat this step again.
14. The instruction has completed execution. Store the least significant 32 bits.
15. Go to step 12 again for reading out more data.
16. Scan\_N into the IR.
17. 1 into the SCREG.
18. INTEST into the IR.
19. Scan out the contents of the DSCR. This clears the sticky precise Data Abort and sticky imprecise Data Abort flags. If the sticky precise Data Abort is set, this means that during the sequence one of the instructions caused a precise Data Abort. All the instructions that follow are not executed. Register r0 points to the next word to be read, and after the cause for the abort has been fixed the sequence resumes at step 5.

---

**Note**

---

If the sticky imprecise Data Aborts flag is set, an imprecise Data Abort has occurred and the sequence restarts at step 1 after the cause of the abort is fixed and r0 is reloaded.

---

**Host to target transfer**

The DBGTAP debugger can use the following sequence for writing data to the processor memory system. The sequence assumes that the ARM register r0 contains a pointer to the address of memory at which the write has to start:

1. Scan\_N into the IR.
2. 1 into the SCREG.
3. INTEST into the IR.
4. Scan out the contents of the DSCR. This clears the sticky precise Data Abort and sticky imprecise Data Abort flags.
5. Scan\_N into the IR.
6. 4 into the SCREG.
7. EXTEST into the IR.
8. Scan in the STC p14, c5, [R0], #4 instruction into the ITR.
9. Scan\_N into the IR.
10. 5 into the SCREG.
11. EXTEST into the IR.
12. Scan in 34 bits, the least significant 32 holding the word to be sent. At the same time, 34 bits are scanned out. If the Ready flag is clear, repeat this step.
13. Go through Run-Test/Idle state.
14. Go to step 12 again for writing in more data.
15. Scan in 34 bits. All the values are don't care. At the same time, 34 bits are scanned out. If the Ready flag is clear, repeat this step. The don't care value is written into the rDTR (Update-DR state) after Ready is seen set (Capture-DR state). However, the STC instruction is not re-issued because the DBGTAPSM does not go through Run-Test/Idle.

16. Scan\_N into the IR.
17. 1 into the SCREG.
18. INTEST into the IR.
19. Scan out the contents of the DSCR. This clears the sticky precise Data Abort and sticky imprecise Data Abort flags. If the sticky precise Data Abort is set, this means that during the sequence one of the instructions caused a precise Data Abort. All the instructions that follow are not executed. Register r0 points to the next word to be written, and after the cause for the abort has been fixed the sequences resumes at step 5.

———— **Note** —————

If the sticky imprecise Data Abort flag is set, an imprecise Data Abort has occurred and the sequence restarts at step 1 after the cause of the abort is fixed and c0 is reloaded.

—————

## 14.8 Debug sequences

This section describes how to debug a program running on the ARM1156T2F-S processor using a DBGTAP debugger device such as RealView ICE. In Halting debug-mode, the processor stops when a debug event occurs enabling the DBGTAP debugger to do the following:

1. Determine and modify the current state of the processor and memory.
2. Set up breakpoints, watchpoints, and vector catches.
3. Restart the processor.

You enable this mode by setting CP14 debug DSCR[14] bit, which can only be done by the DBGTAP debugger. From here it is assumed that the debug unit is in Halting debug-mode. Monitor debug-mode debugging is described in *Monitor debug-mode debugging* on page 14-50.

### 14.8.1 Debug macros

The debug code sequences in this section are written using a fixed set of macros. The mapping of each macro into a debug scan chain sequence is given in this section.

#### **Scan\_N <n>**

Select scan chain register number <n>:

1. Scan the Scan\_N instruction into the IR.
2. Scan the number <n> into the DR.

#### **INTEST**

1. Scan the INTEST instruction into the IR.

#### **EXTEST**

1. Scan the EXTEST instruction into the IR.

#### **ITRsel**

1. Scan the ITRsel instruction into the IR.

#### **Restart**

1. Scan the Restart instruction into the IR.

2. Go to the DBGTAP controller Run-Test/Idle state so that the processor exits Debug state.

### **INST <instr> [stateout]**

Go through Capture-DR, go to Shift-DR, scan in an ARM instruction to be read and executed by the core and scan out the Ready flag, go through Update-DR. The ITR (scan chain 4) and EXTEST must be selected when using this macro.

1. Scan in:
  - Any value for the InstCompl flag. This bit is read-only.
  - 32-bit assembled code of the instruction (instr) to be executed, for ITR[31:0].
2. The following data is scanned out:
  - The value of the Ready flag, to be stored in stateout.
  - 32 bits to be ignored. The ITR is write-only.

### **DATA <datain> [<stateout> [dataout]]**

Go through Capture-DR, go to Shift-DR. Scan in a data item and scan out another one, go through Update-DR. Either the DTR (scan chain 5) or the DSCR (scan chain 1) must be selected when using this macro.

1. If scan chain 5 is selected, scan in:
  - Any value for the nRetry or Valid flag. These bits are read-only.
  - Any value for the InstCompl flag. This bit is read-only.
  - 32-bit datain value for rDTR[31:0].
2. The following data is scanned out:
  - The contents of wDTR[31:0], to be stored in dataout.
  - If the DSCR[13] execute ARM instruction enable bit is set, the value of the Ready flag is stored in stateout.
  - If the DSCR[13] execute ARM instruction enable bit is clear, the nRetry or Valid flag (depending on whether EXTEST or INTEST is selected) is stored in stateout.
3. If scan chain 1 is selected, scan in:
  - 32-bit datain value for DSCR[31:0].

Stateout and dataout fields are not used in this case.

**DATAOUT <dataout>**

1. Scan out a data value. DSCR (scan chain 1) and INTEST must be selected when using this macro.
2. If scan chain 1 is selected, scan out the contents of the DSCR, to be stored in dataout.
3. The scanned-in value is discarded, because INTEST is selected.

**REQ <address> <data> <nR/W> [<stateout> [dataout]]**

Go through Capture-DR, go to Shift-DR, scan in a request and scan out the result of the former one, go through Update-DR. Scan chain 7, and either INTEST or EXTEST, must be selected when using this macro.

1. Scan in:
  - 7-bit address value for Address[6:0]
  - 32-bit data value for Data[31:0]
  - 1-bit nR/W value (0 for read and 1 for write) for the Ready/nRW field.
2. Scan out:
  - the value of the Ready/nRW bit, to be stored in stateout
  - the contents of the Data field, to be stored in dataout.

**RTI**

1. Go through Run-Test/Idle DBG TAPSM state. This forces the execution of the instruction currently loaded into the ITR, provided the execute ARM instruction enable bit (DSCR[13]) is set, the Ready flag was captured as set, and the sticky precise Data Abort flag is cleared.

**14.8.2 General setup**

You must setup the following control bits before DBG TAP debugging can take place:

- DSCR[14] Halt/Monitor debug-mode bit must be set to 1. It resets to 0 on power-up.
- DSCR[6] sticky precise Data Abort flag must be cleared down, so that aborts are not detected incorrectly immediately after startup.

The DSCR must be read, the DSCR[14] bit set, and the new value written back. The action of reading the DSCR automatically clears the DSCR[6] sticky precise Data Abort flag. All individual breakpoints, watchpoints, and vector catches reset disabled on power-up.

### 14.8.3 Forcing the processor to halt

Scan the Halt instruction into the DBGTAP controller IR and go through Run-Test/Idle.

### 14.8.4 Entering Debug state

To enter Debug state you must:

1. Check whether the core has entered Debug state, as follows:
 

```
SCAN_N 1 ; select DSCR
INTEST
LOOP
 DATAOUT readDSCR
UNTIL readDSCR[0]==1 ; until Core Halted bit is set
```
2. Save DSCR, as follows:
 

```
DATAOUT readDSCR
Save value in readDSCR
```
3. Save wDTR (in case it contains some data), as follows:
 

```
SCAN_N 5 ; select DTR
INTEST
DATA 0x00000000 Valid wDTR
If Valid==1 then Save value in wDTR
```
4. Set the DSCR[13] execute ARM instruction enable bit, so instructions can be issued to the core from now:
 

```
SCAN_N 1 ; select DSCR
EXTEST
DATA modifiedDSCR ; modifiedDSCR equals readDSCR with bit
 ; DSCR[13] set
```
5. Before executing any instruction in Debug state you have to drain the write buffer. This ensures that no imprecise Data Aborts can return at a later point:
 

```
SCAN_N 4 ; select DTR
INST MRC p14, 0, Rd, c5, c10, 0 ; drain write buffer
LOOP
 LOOP
 SCAN_N 4 ; select DTR
 RTI
 INST 0x0 Ready
```

```

 Until Ready == 1
 SCAN_N 1
 DATAOUT readDSCR
Until readDSCR[7]==1
SCAN_N 4
INST NOP ; NOP takes the
RTI ; imprecise Data Aborts
LOOP
 INST 0 Ready
Until Ready == 1
SCAN_N 1
DATAOUT readDSCR ; clears DSCR[7]

```

6. Store out r0. It is going to be used to save the rDTR. Use the standard sequence described in *Reading a current mode ARM register in the range r0-r14* on page 14-40. Scan chain 5 and INTEST are now selected.
7. Save the rDTR and the rDTRempty bit in three steps:
  - a. The rDTRempty bit is the inverted version of DSCR[30] (saved in step 2). If DSCR[30] is clear (register empty) there is no requirement to read the rDTR, go to 7.
  - b. Transfer the contents of rDTR to r0:
 

```

 ITRSEL ; select the ITR and EXTEST
 INST MRC p14, 0, R0, c0, c5, 0 ; instruction to copy CP14's debug
 ; register c5 into R0
 RTI
 LOOP
 INST 0x00000000 Ready
 UNTIL Ready==1 ; wait until the instruction ends

```
  - c. Read r0 using the standard sequence described in *Reading a current mode ARM register in the range r0-r14* on page 14-40.
8. Store out CPSR using the standard sequence described in *Reading the CPSR/SPSR* on page 14-41.
9. Store out PC using the standard sequence described *Reading the PC* on page 14-42.
10. Adjust the PC to enable you to resume execution later:
  - subtract 0x8 from the stored value if the processor was in ARM state when entering Debug state
  - subtract 0x4 from the stored value if the processor was in Thumb state when entering Debug state.

These values are not dependent on the Debug state entry method, see *Behavior of the PC in Debug state* on page 13-36. The entry state can be determined by examining the T bit of the CPSR.

11. Cache and MPU preservation measures must also be taken here. This includes saving all the relevant CP15 registers using the standard coprocessor register reading sequence described in *Coprocessor register reads and writes* on page 14-46.

### 14.8.5 Leaving Debug state

To leave Debug state:

1. Restore standard ARM registers for all modes, except r0, PC, and CPSR.
2. Cache and MPU restoration must be done here. This includes writing the saved registers back to CP15.
3. Ensure that rDTR and wDTR are empty:
 

```

ITRSEL ; select the ITR and EXTEST
INST MCR p14, 0, R0, c0, c5, 0 ; instruction to copy R0 into
 ; CP14 debug register c5

RTI
LOOP
 INST 0x00000000 Ready
UNTIL Ready==1 ; wait until the instruction ends
SCAN_N 5
INTEST
DATA 0x0 Valid wDTR

```
4. If the wDTR did not contain any valid data on Debug state entry go to step 5. Otherwise, restore wDTRfull and wDTR (uses r0 as a temporary register) in two steps.

- a. Load the saved wDTR contents into r0 using the standard sequence described in *Writing a current mode ARM register in the range r0-r14* on page 14-41. Now scan chain 5 and EXTEST are selected

- b. Transfer r0 into wDTR:

```

ITRSEL ; select the ITR and EXTEST
INST MCR p14, 0, R0, c0, c5, 0 ; instruction to copy R0 into
 ; CP14 debug register c5

RTI
LOOP
 INST 0x00000000 Ready
UNTIL Ready==1 ; wait until the instruction ends

```

5. Restore CPSR using the standard CPSR writing sequence described in *Writing the CPSR/SPSR* on page 14-42.
6. Restore the PC using the standard sequence described in *Writing the PC* on page 14-42.
7. Restore r0 using the standard sequence described in *Writing a current mode ARM register in the range r0-r14* on page 14-41. Now scan chain 5 and EXTEST are selected.
8. Restore the DSCR with the DSCR[13] execute ARM instruction enable bit clear, so no more instructions can be issued to the core:
 

```
SCAN_N 1 ; select DSCR
EXTEST
DATA modifiedDSCR ; modifiedDSCR equals the saved contents
; of the DSCR with bit DSCR[13] clear
```
9. If the rDTR did not contain any valid data on Debug state entry go to step 10. Otherwise, restore the rDTR and rDTRempty flag:
 

```
SCAN_N 5 ; select DTR
EXTEST
DATA Saved_rDTR ; rDTRempty bit is automatically cleared
; as a result of this action
```
10. Restart processor:
 

```
RESTART
```
11. Wait until the core is restarted:
 

```
SCAN_N 1 ; select DSCR
INTEST
LOOP
DATAOUT readDSCR
UNTIL readDSCR[1]==1 ; until Core Restarted bit is set
```

#### 14.8.6 Reading a current mode ARM register in the range r0-r14

Use the following sequence to read a current mode ARM register in the range r0-r14:

```
SCAN_N 5 ; select DTR
ITRSEL ; select the ITR and EXTEST
INST MCR p14, 0, Rd, c0, c5, 0 ; instruction to copy Rd into CP14 debug
; register c5
RTI
INTEST ; select the DTR and INTEST
LOOP
DATA 0x00000000 Ready readData
UNTIL Ready==1 ; wait until the instruction ends
```

Save value in readData

---

**Note**

---

Register r15 cannot be read in this way because the effect of the required MCR is to take an Undefined exception.

---

### 14.8.7 Writing a current mode ARM register in the range r0-r14

Use the following sequence to write a current mode ARM register in the range r0-r14:

```

SCAN_N 5 ; select DTR
ITRSEL ; select the ITR and EXTEST
INST MRC p14, 0, Rd, c0, c5, 0 ; instruction to copy CP14 debug
 ; register c5 into RdEXTEST
 ; select the DTR and EXTEST

DATA Data2Write
RTI
LOOP
 DATA 0x00000000 Ready
UNTIL Ready==1 ; wait until the instruction ends

```

---

**Note**

---

Register r15 cannot be written in this way because the MRC instruction used would update the CPSR flags rather than the PC.

---

### 14.8.8 Reading the CPSR/SPSR

Here r0 is used as a temporary register:

1. Move the contents of CPSR/SPSR to r0.

```

SCAN_N 5 ; select DTR
ITRSEL ; select the ITR and EXTEST
INST MRS R0,CPSR ; or SPSR
RTI
LOOP
 INST 0x00000000 Ready
UNTIL Ready==1 ; wait until the instruction ends

```

2. Perform the read of r0 using the standard sequence described in *Reading a current mode ARM register in the range r0-r14* on page 14-40. Scan chain 5 and ITRsel are already selected.

### 14.8.9 Writing the CPSR/SPSR

Here r0 is used as a temporary register:

1. Load the desired value into r0 using the standard sequence described in *Writing a current mode ARM register in the range r0-r14* on page 14-41. Now scan chain 5 and EXTEST are selected.

2. Move the contents of r0 to CPRS/SPRS:

```

ITRSEL ; select the ITR and EXTEST
INST MSR CPSR,R0 ; or SPSR
RTI
LOOP
 INST 0x00000000 Ready
UNTIL Ready==1 ; wait until the instruction ends

```

It is not a problem to write to the T bit because they have no effect in the execution of instructions while in Debug state.

The CPSR mode and control bits can be written in User mode when the core is in Debug state. This is essential so that the debugger can change mode and then get at the other banked registers.

### 14.8.10 Reading the PC

Here r0 is used as a temporary register:

1. Move the contents of the PC to r0:

```

ITRSEL ; select the ITR and EXTEST
INST MOV R0,PC
RTI
LOOP
 INST 0x00000000 Ready
UNTIL Ready==1 ; wait until the instruction ends

```

2. Read the contents of r0 using the standard sequence described in *Reading a current mode ARM register in the range r0-r14* on page 14-40.

### 14.8.11 Writing the PC

Here r0 is used as a temporary register:

1. Load r0 with the address to resume using the standard sequence described in *Writing a current mode ARM register in the range r0-r14* on page 14-41. Now scan chain 5 and EXTEST are selected.
2. Move the contents of r0 to the PC:

```

ITRSEL ; select the ITR and EXTEST
INST MOV PC,R0
RTI
LOOP
 INST 0x00000000 Ready
UNTIL Ready==1 ; wait until the instruction ends

```

### 14.8.12 General notes about reading and writing memory

On the ARM1156T2F-S processor, an abort occurring in Debug state causes an Abort exception entry sequence to start, and so changes mode to Abort mode, and writes to r14\_abt and SPSR\_abt. This means that the Abort mode registers must be saved before performing a Debug state memory access. The word-based read and write sequences are substantially more efficient than the halfword and byte sequences. This is because the ARM LDC and STC instructions always perform word accesses, and this can be used for efficient access to word width memory. Halfword and byte accesses must be done with a combination of loads or stores, and coprocessor register transfers, which is much less efficient. When writing data, the instruction cache might become incoherent. In those cases, either a line or the whole instruction cache must be invalidated. In particular, the instruction cache must be invalidated before setting a software breakpoint or downloading code.

### 14.8.13 Reading memory as words

This sequence is optimized for a long sequential read. This sequence assumes that r0 has been set to the address to load data from prior to running this sequence. r0 is post-incremented so that it can be used by successive reads of memory.

1. Load and issue the LDC instruction:

```

SCAN_N 5 ; select DTR
ITRSEL ; select the ITR and EXTEST
INST LDC p14, c5, [R0], #4 ; load the content of the position of
 ; memory pointed by R0 into wDTR and
 ; increment R0 by 4
RTI

```

2. The DTR is selected to read the data:

```

INTEST ; select the DTR and INTEST

```

3. This loop keeps on reading words, but it stops before the latest read. It is skipped if there is only one word to read:

```

FOR(i=1; i <= (Words2Read-1); i++) DO
 LOOP
 DATA 0x00000000 Ready readData ; gets the result of
 ; the previous read
 RTI ; issues the next read

```

```

UNTIL Ready==1 ; wait until the instruction ends
Save value in readData
ENDFOR

```

4. Wait for the last read to finish:

```

LOOP
 DATA 0x00000000 Ready readData
UNTIL Ready==1 ; wait until instruction ends
Save value in readData

```

5. Now check whether an abort occurred:

```

SCAN_N 1 ; select DSCR
INTEST
DATAOUT DSCR ; this action clears the DSCR[6] flag

```

6. Scan out the contents of the DSCR. This clears the sticky precise Data Abort and sticky imprecise Data Abort flags. If the sticky precise Data Abort is set, this means that during the sequence one of the instructions caused a precise Data Abort. All the instructions that follow are not executed. Register r0 points to the next word to be written, and after the cause for the abort has been fixed the sequences resumes at step 1.

———— **Note** ————

If the sticky imprecise Data Aborts flag is set, an imprecise Data Abort has occurred and the sequence restarts at step 1 after the cause of the abort is fixed and r0 is reloaded.

—————

#### 14.8.14 Writing memory as words

This sequence is optimized for a long sequential write. This sequence assumes that r0 has been set to the address to store data to prior to running this sequence. Register r0 is post-incremented so that it can be used by successive writes to memory:

1. The instruction is loaded:

```

SCAN_N 5 ; select DTR
ITRSEL ; select the ITR and EXTEST
INST STC p14, c5, [R0], #4 ; store the contents of rDTR into the
 ; position of memory pointed by R0 and
 ; increment it by 4
EXTEST ; select the DTR and EXTEST

```

2. This loop writes all the words:

```

FOR (i=1; i <= Words2Write; i++) DO
 LOOP
 DATA Data2Write Ready

```

```

RTI
UNTIL Ready==1 ; wait until instruction ends
ENDFOR

```

3. Wait for the last write to finish:

```

LOOP
 DATA 0x00000000 Ready
UNTIL Ready==1 ; wait until instruction ends

```

4. Check for aborts, as described in *Reading memory as words* on page 14-43.

### 14.8.15 Reading memory as halfwords or bytes

Steps 1. to 4. in *Reading memory as words* on page 14-43 cannot be used to transfer halfwords or bytes because LDC and STC instructions always transfer whole words. Two operations are required to complete a halfword or byte transfer, from memory to ARM register and from ARM register to CP14 debug register. Therefore, performance is decreased because the load instruction cannot be kept in the ITR. This sequence assumes that r0 has been set to the address to load data from prior to running the sequence. Register r0 is post-incremented so that it can be used by successive reads of memory. Register r1 is used as a temporary register:

1. Load and issue the LDRH or LDRB instruction:

```

ITRSEL ; select the ITR and EXTEST
INST LDRH R1,[R0],#2 ; LDRB R1,[R0],#1 for byte reads
RTI
LOOP
 INST 0x00000000 Ready
UNTIL Ready==1 ; wait until instruction ends

```

2. Use the standard sequence described in *Reading a current mode ARM register in the range r0-r14* on page 14-40 on register r1. Now scan chain 5 and INTEST are selected.
3. If there are more halfwords or bytes to be read go to 1.
4. Check for aborts, as described in *Reading memory as words* on page 14-43.

### 14.8.16 Writing memory as halfwords/bytes

This sequence assumes that r0 has been set to the address to store data to prior to running this sequence. Register r0 is post-incremented so that it can be used by successive writes to memory. Register r1 is used as a temporary register:

1. Write the halfword/byte onto r1 using the standard sequence described in *Writing a current mode ARM register in the range r0-r14* on page 14-41. Scan chain 5 and EXTEST are selected.
2. Write the contents of r1 to memory:
 

```

ITRSEL ; select the ITR and EXTEST
INST STRH R1,[R0],#2 ; STRB R1,[R0],#1 for byte writes
RTI
LOOP INST 0x00000000 Ready
UNTIL Ready==1 ; wait until instruction ends

```
3. If there are more halfwords or bytes to be read go to 1.
4. Now check for aborts as described in *Reading memory as words* on page 14-43.

### 14.8.17 Coprocessor register reads and writes

The ARM1156T2F-S processor can execute coprocessor instructions while in Debug state. Therefore, the straightforward method to transfer data between a coprocessor and the DBGTap debugger is using an ARM register temporarily. For this method to work, the coprocessor must be able to transfer all its registers to the core using coprocessor transfer instructions.

### 14.8.18 Reading coprocessor registers

1. Load the value into ARM register r0:
 

```

ITRSEL ; select the ITR and EXTEST
INST MRC px, y, R0, ca, cb, z
RTI
LOOP
 INST 0x00000000 Ready
UNTIL Ready==1 ; wait until instruction ends

```
2. Use the standard sequence described in *Reading a current mode ARM register in the range r0-r14* on page 14-40.

### 14.8.19 Writing coprocessor registers

1. Write the value onto r0, using the standard sequence. See *Writing a current mode ARM register in the range r0-r14* on page 14-41 for more details. Scan chain 5 and EXTEST are selected.
2. Transfer the contents of r0 to a coprocessor register:
 

```

 ITRSEL ; select the ITR and EXTEST
 INST MCR px, y, 0, ca, cb, z
 RTI
 LOOP
 INST 0x00000000 Ready
 UNTIL Ready==1 ; wait until instruction ends

```

## 14.9 Programming debug events

The following operations are described:

- *Reading registers using scan chain 7*
- *Writing registers using scan chain 7*
- *Setting breakpoints, watchpoints and vector catches on page 14-49*
- *Setting software breakpoints on page 14-49.*

### 14.9.1 Reading registers using scan chain 7

A typical sequence for reading registers using scan chain 7 is as follows:

```

SCAN_N 7 ; select ITR
EXTTEST
REQ 1stAddr2Rd 0 0 ; read request for register 1stAddr2read
FOR(i=2; i <= Words2Read; i++) DO
 LOOP
 REQ itAADDR2Rd 0 0 Ready readData
 ; read request while waiting
 UNTIL Ready==1 ; wait until the previous request completes
 Save value in readData
 ENDFOR
 LOOP
 REQ 0 0 0 Ready readData ; null request while waiting
 UNTIL Ready==1 ; wait until last request completes
 Save value in readData

```

### 14.9.2 Writing registers using scan chain 7

A typical sequence for writing to a register using scan chain 7 is as follows:

```

SCAN_N 7 ; select ITR
EXTTEST
REQ 1stAddr2Wr 1stData2Wr 0b1 ; write request for register 1stAddr2write
FOR(i=2; i <= Words2Write; i++) DO
 LOOP
 REQ itAADDR2Wr ithData2Wr 1 Read
 ; write request while waiting
 UNTIL Ready==1 ; wait until the previous request completes
 ENDFOR
 LOOP
 REQ 0 0 0 Ready
 UNTIL Ready==1 ; wait until last request completes

```

### 14.9.3 Setting breakpoints, watchpoints and vector catches

You can program a vector catch debug event by writing to CP14 debug vector catch register.

You can program a breakpoint debug event by writing to CP14 debug 64-69 breakpoint value registers and CP14 debug 80-84 Breakpoint Control Registers.

You can program a watchpoint debug event by writing to CP14 debug 96-97 watchpoint value registers and CP14 debug 112-113 Watchpoint Control Registers.

---

**Note**

An External Debugger can access the CP14 debug registers whether the processor is in Debug state or not, so these debug events can be programmed on-the-fly while the processor is in ARM state or Thumb state.

---

See *Setting breakpoints, watchpoints, and vector catch debug events* on page 13-41 for the sequences of register accesses required to program these software debug events. See *Writing registers using scan chain 7* on page 14-48 to learn how to access CP14 debug registers using scan chain 7.

### 14.9.4 Setting software breakpoints

To set a software breakpoint on a certain physical address, a debugger must go through the following steps:

1. Read memory location and save actual instruction.
2. Write the BKPT instruction to the memory location.
3. Read memory location again to check that the BKPT instruction got written.
4. If it is not written, determine the reason.

All of these can be done using the previously described sequences.

---

**Note**

Cache coherency issues might arise when writing a BKPT instruction. See *Debugging in a cached system* on page 13-40.

---

## 14.10 Monitor debug-mode debugging

If DSCR[14] Halt/Monitor debug-mode bit is clear, then the processor takes an exception (rather than halting) when a software debug event occurs. See *Halting debug-mode debugging* on page 13-47 for details. When the exception is taken, the handler uses the DCC to transmit status information to, and receive commands from the host using a DBGTap debugger. Monitor debug-mode is essential in real-time systems when the core cannot be halted to collect information.

### 14.10.1 Receiving data from the core

```

SCAN_N 5 ; select DTR
INTEST
FOREACH Data2Read
 LOOP
 DATA 0x00000000 Valid readData
 UNTIL Valid==1 ; wait until instruction ends
 Save value in readData
END

```

### 14.10.2 Sending data to the core

```

SCAN_N 5 ; select DTR
EXTEST
FOREACH Data2Write
 LOOP
 DATA Data2Write nRetry
 UNTIL nRetry==1 ; wait until instruction ends
END

```

# Chapter 15

## Trace Interface Port

This chapter gives a brief description of the *EmbeddedTraceMacrocell* (ETM) support for the ARM1156T2F-S processor. It contains the following section:

- *About the ETM interface* on page 15-2.

## 15.1 About the ETM interface

The ARM1156T2F-S trace interface port enables connection of an ETM11 to an ARM1156T2F-S processor. The ARM *Embedded Trace Macrocell* (ETM) provides instruction and data trace for the ARM11 family of processors. For more details on how the ETM interface connects to an ARM11 processor, see *CoreSight ETM11 Technical Reference Manual*.

All inputs are registered immediately inside the ETM unless specified otherwise. All outputs are driven directly from a register unless specified otherwise. All signals are relative to **CLKIN** unless specified otherwise.

The ETM interface includes the following groups of signals:

- an instruction interface
- a data address interface
- a pipeline advance interface
- a data value interface
- a coprocessor interface
- other connections to the core.

### 15.1.1 Instruction interface

The primary sampling point for these signals is on entry to write-back. See *Typical pipeline operations* on page 1-25. This ensures that instructions are traced correctly before any data transfers associated with them, as required by the ETM protocol. Table 15-1 shows the signals of the instruction address interface.

**Table 15-1 Instruction interface signals**

| Signal name           | Description                                                                                | Qualified by     |
|-----------------------|--------------------------------------------------------------------------------------------|------------------|
| <b>ETMICTL[17:0]</b>  | Instruction interface control signals                                                      | -                |
| <b>ETMIA[31:0]</b>    | This is the address for:<br>ARM executed instruction + 8<br>Thumb executed instruction + 4 | <b>IAValid</b>   |
| <b>ETMIARET[31:0]</b> | Address to return to if branch is incorrectly predicted                                    | <b>IABpValid</b> |

Other than this the ETM must know, for each cycle, the current address of the instruction in execute and the address of any branch phantom progressing through the pipeline. The ARM1156T2F-S processor does not maintain the address of branch phantoms, instead it maintains the address to return to if the branch proves to be incorrectly predicted.

**ETMIA** is used for branch target address calculation.

The instruction interface can trace a branch phantom without an associated normal instruction.

In the case of a branch that is predicted taken, the return address (for when the branch is not taken) is one instruction after the branch. Therefore, the branch address is:

$$\text{ETMIABP} = \text{ETMIARET} - \langle \text{size} \rangle$$

When the instruction is predicted not taken, the return address is the target of the branch. However, because the branch was not taken, it must precede the normal instruction. Therefore, the branch address is:

$$\text{ETMIABP} = \text{ETMIA} - \langle \text{size} \rangle$$

Table 15-2 shows the how the bits correspond to **ETMIACTL[17:0]** signal of the instruction interface.

**Table 15-2 ETMIACTL[17:0]**

| Bits    | Reference name      | Description                                                                                                                                    | Qualified by       |
|---------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| [17]    | <b>IASlotKill</b>   | Kill outstanding slots.                                                                                                                        | <b>IAException</b> |
| [16]    | <b>IADAbort</b>     | Data Abort.                                                                                                                                    | <b>IAException</b> |
| [15]    | <b>IAExCancel</b>   | Exception canceled previous instruction.                                                                                                       | <b>IAException</b> |
| [12:14] | <b>IAExInt</b>      | b001 = IRQ<br>b101 = FIQ<br>b110 = Imprecise Data Abort<br>b000 = Other exception.                                                             | <b>IAException</b> |
| [11]    | <b>IAException</b>  | Instruction is an exception vector.                                                                                                            | None <sup>a</sup>  |
| [10]    | <b>IABounce</b>     | Kill the data slot associated with this instruction. There is only ever one of these instructions. Used for bouncing coprocessor instructions. | <b>IADDataInst</b> |
| [9]     | <b>IADDataInst</b>  | Instruction is a data instruction. This includes any load, store, or CPRT, but does not include preloads.                                      | <b>IAInstValid</b> |
| [8]     | <b>IAContextID</b>  | Instruction updates Process ID.                                                                                                                | <b>IAInstValid</b> |
| [7]     | <b>IAIndBr</b>      | Instruction is an indirect branch.                                                                                                             | <b>IAInstValid</b> |
| [6]     | <b>IABpCCFail</b>   | Branch phantom failed its condition codes.                                                                                                     | <b>IABpValid</b>   |
| [5]     | <b>IAInstCCFail</b> | Instruction failed its condition codes.                                                                                                        | <b>IAInstValid</b> |

Table 15-2 ETMICTL[17:0] (continued)

| Bits | Reference name     | Description                                                                                               | Qualified by   |
|------|--------------------|-----------------------------------------------------------------------------------------------------------|----------------|
| [4]  | Reserved           | Not used in this processor.                                                                               | -              |
| [3]  | <b>IATBit</b>      | Instruction executed in Thumb state.                                                                      | <b>IAValid</b> |
| [2]  | <b>IABpValid</b>   | Branch phantom executed this cycle.                                                                       | <b>IAValid</b> |
| [1]  | <b>IAInstValid</b> | (Non-phantom) instruction executed this cycle.                                                            | <b>IAValid</b> |
| [0]  | <b>IAValid</b>     | Signals on the instruction interface are valid this cycle. This is kept LOW when the ETM is powered down. | None           |

- a. The exception signals become valid when the core takes the exception and remain valid until the next instruction is seen at the exception vector.

15.1.2 Data address interface

Data addresses are sampled at the load/store ADD stage because they are guaranteed to be in order at this point. These are assigned a slot number for identification on retirement.

Table 15-3 shows the signals of the data address interface.

Table 15-3 Data address interface signals

| Signal name    | Description                            | Qualified by                           |
|----------------|----------------------------------------|----------------------------------------|
| ETMDACTL[17:0] | Data address interface control signals | -                                      |
| ETMDA[31:3]    | Address for data transfer              | <b>DASlot</b> != 00 AND <b>!DACPRT</b> |

Table 15-4 shows the how the bits correspond to **ETMDACTL[17:0]** signal of the data address interface.

**Table 15-4 ETMDACTL[17:0]**

| <b>Bits</b> | <b>Reference name</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                 | <b>Qualified by</b> |
|-------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| [17]        | <b>DANSeq</b>         | The data transfer is nonsequential from the last. This signal must be asserted on the first cycle of each instruction, in addition to the second transfer of a SWP or LDM PC, because the address of these transfers is not one word greater than the previous transfer, and therefore the transfer must have its address re-output.<br>During an unaligned access, this signal is only valid on the first transfer of the access. | <b>DASlot</b> != 00 |
| [16]        | <b>DALast</b>         | The data transfer is the last for this data instruction. This signal is asserted for both halves of an unaligned access.<br>A related signal, DAFirst, can be implied from this signal, because the next transfer must be the first transfer of the next data instruction.                                                                                                                                                         | <b>DASlot</b> != 00 |
| [15]        | <b>DACPRT</b>         | The data transfer is a CPRT.                                                                                                                                                                                                                                                                                                                                                                                                       | <b>DASlot</b> != 00 |
| [14]        | <b>DASwizzle</b>      | Words must be byte swizzled for ARM big-endian mode.<br>During an unaligned access, this signal is only valid on the first transfer of the access.                                                                                                                                                                                                                                                                                 | <b>DASlot</b> != 00 |
| [13:12]     | <b>DARot</b>          | Number of bytes to rotate right each word by.<br>During an unaligned access, this signal is only valid on the first transfer of the access.                                                                                                                                                                                                                                                                                        | <b>DASlot</b> != 00 |
| [11]        | <b>DAUnaligned</b>    | First transfer of an unaligned access.<br>The next transfer must be the second half, for which this signal is not asserted.                                                                                                                                                                                                                                                                                                        | <b>DASlot</b> != 00 |
| [10:3]      | <b>DABLSel</b>        | Byte lane selects.                                                                                                                                                                                                                                                                                                                                                                                                                 | <b>DASlot</b> != 00 |
| [2]         | <b>DAWrite</b>        | Read or write.<br>During an unaligned access, this signal is only valid on the first transfer of the access.                                                                                                                                                                                                                                                                                                                       | <b>DASlot</b> != 00 |
| [1:0]       | <b>DASlot</b>         | Slot occupied by data item.<br>b00 indicates that no slot is in use this cycle.<br>b01, b10, b11 indicates a slot is in use this cycle.                                                                                                                                                                                                                                                                                            | None                |

15.1.3 Data value interface

The data values are sampled at the WBIs stage. Here the load, store, MCR, and MRC data is combined. The memory view of the data is presented, which must be converted back to the register view depending on the alignment and endianness.

Data is not returned for at least two cycles after the address. However, it is not necessary to pipeline the address because the slot does not return data for a previous address during this time. Data values are defined to correspond to the most recent data addresses with the same slot number, starting from the previous cycle. That is, data can correspond to an address from the previous cycle, but not to an address from the same cycle.

Table 15-5 shows the signals of the data value interface.

Table 15-5 Data value interface signals

| Signal name   | Description                                                  | Qualified by |
|---------------|--------------------------------------------------------------|--------------|
| ETMDDCTL[3:0] | Data value interface control signals                         | -            |
| ETMDD[63:0]   | Contains the data for a load, store, MRC, or MCR instruction | DDSlot != 00 |

Table 15-6 shows the how the bits correspond to ETMDDCTL[3:0] signal of the data value interface.

Table 15-6 ETMDDCTL[3:0]

| Bits  | Reference name | Description                                                                                                                             | Qualified by |
|-------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------|--------------|
| [3]   | DDImpAbort     | Imprecise Data Aborts on this slot. Data is ignored.                                                                                    | DDSlot != 00 |
| [2]   | DDFail         | STREX data write failed.                                                                                                                | DDSlot != 00 |
| [1:0] | DDSlot         | Slot occupied by data item.<br>b00 indicates that no slot is in use this cycle.<br>b01, b10, b11 indicates a slot is in use this cycle. | None         |

15.1.4 Pipeline advance interface

There are three points in the ARM1156T2F-S pipeline at which signals are produced for the ETM. These signals must be realigned by the ETM, so pipeline advance signals are provided.

The pipeline advance signals indicate when a new instruction enters pipeline stages Ex3, Ex2, and load/store ADD, see *Typical pipeline operations* on page 1-25.

Table 15-7 shows the pipeline advance interface signals **ETMPADV[2:0]**.

Table 15-7 ETMPADV[2:0]

| Bits | Reference name           | Description                                      | Qualified by |
|------|--------------------------|--------------------------------------------------|--------------|
| [2]  | <b>PAEx3<sup>a</sup></b> | Instruction entered Ex3 stage                    | -            |
| [1]  | <b>PAEx2<sup>a</sup></b> | Instruction entered Ex2 stage                    | -            |
| [0]  | <b>PAAdd<sup>a</sup></b> | Instruction entered Ex1 and load/store ADD stage | -            |

a. This is kept LOW when the ETM is powered down.

The pipeline advance signals present in other interfaces are:

|                     |                             |
|---------------------|-----------------------------|
| <b>IAValid</b>      | Instruction entered WBEx.   |
| <b>DASlot != 00</b> | Data transfer entered DC1.  |
| <b>DDSlot != 00</b> | Data transfer entered WBIs. |

### 15.1.5 Coprocessor interface

This interface enables an ETM to monitor a sub-set of CP14 and CP15 operations. Rather than using the external coprocessor interface, the core provides a dedicated, cut-down coprocessor interface similar to that used by the debug logic.

Table 15-8 shows the coprocessor interface signals.

Table 15-8 Coprocessor interface signals

| Signal name        | Direction | Description                                                                                                                             | Qualified by          | Reg bound |
|--------------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------|-----------------------|-----------|
| <b>ETMCPENABLE</b> | Output    | Interface enable. <b>ETMCPWRITE</b> and <b>ETMCPADDRESS</b> are valid this cycle, and the remaining signals are valid two cycles later. | None                  | Yes       |
| <b>ETMCPCOMMIT</b> | Output    | Commit. If this signal is LOW two cycles after <b>ETMCPENABLE</b> is asserted, the transfer is canceled and must not take any effect.   | <b>ETMCPENABLE</b> +2 | Yes       |
| <b>ETMCPWRITE</b>  | Output    | Read or write. Asserted for write.                                                                                                      | <b>ETMCPENABLE</b>    | Yes       |

Table 15-8 Coprocessor interface signals (continued)

| Signal name        | Direction | Description      | Qualified by | Reg bound |
|--------------------|-----------|------------------|--------------|-----------|
| ETMCPADDRESS[14:0] | Output    | Register number. | ETMCPENABLE  | Yes       |
| ETMCPRDATA[31:0]   | Input     | Read data.       | ETMCPCOMMIT  | Yes       |
| ETMCPWDATA[31:0]   | Output    | Write value.     | ETMCPCOMMIT  | Yes       |

A complete transaction takes three cycles. The first and last cycles can overlap, giving a sustained rate of one every two cycles.

**Note**

Because current *Embedded Trace Macrocells* (ETMs) do not use the **ETMCPRDATA[31:0]** signal you must ensure that the signal is tied off to 0x00000000.

Only the following instructions are presented by the coprocessor interface:

- MRC p14, 1, <Rd>, c0, <CRm>, <op2>
- MCR p14, 1, <Rd>, c0, <CRm>, <op2>
- MCR p15, 0, <Rd>, c13, c0, 1

The format of the **ETMCPADDRESS[14:0]** signals are shown in Figure 15-1.

Figure 15-1 ETMCPADDRESS format

In Figure 15-1, the CP bit is 0 for CP14 or 1 for CP15.

### 15.1.6 Other connections to the core

Table 15-9 shows the signals that also connect to the core.

**Table 15-9 Other connections**

| Signal name           | Direction | Description                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EVENTBUS[19:0]</b> | Output    | Gives the status of the performance monitoring events. See <i>System performance monitor</i> on page 3-10.                                                                                                                                                                                                                                                                                                  |
| <b>ETMEXTOUT[1:0]</b> | Input     | Provides feedback to the core of the <b>EVENTBUS</b> signals after being passed through ETM triggering facilities and comparators. This enables the performance monitoring facilities provided by ARM1156T2F-S processors to be conditioned in the same way as ETM events. For more details, see <i>System performance monitor</i> on page 3-10 and the <i>CoreSight ETM11 Technical Reference Manual</i> . |
| <b>ETMPWRUP</b>       | Input     | Indicates that the ETM is active. When LOW the Trace Interface must be clock gated to conserve power.                                                                                                                                                                                                                                                                                                       |

# Chapter 16

## Test Features

This chapter describes the test features of the processor. It contains the following sections:

- *About the test features* on page 16-2
- *Memory BIST* on page 16-3
- *Power-On Test* on page 16-12
- *Running System Test* on page 16-13.

## 16.1 About the test features

The processor test features are:

- memory *Built-In Self Test* (BIST)
- power-on (or key-on for automotive) test
- running system test.

Power-on test and running system test are of particular importance to applications where safety might be compromised through undetected faults. These faults can be accessed through the cache debug and software test access registers of CP15.

## 16.2 Memory BIST

The traditional method of gaining access to a RAM for memory BIST is shown in Figure 16-1.

**Figure 16-1 Traditional method interfacing memory BIST**

This method can cause a significant reduction in the maximum operating frequency of the processor. To avoid this, an additional input to existing multiplexors is added without reducing maximum operating frequency.

Figure 16-2 on page 16-4 shows an alternative method that uses five pipeline stages to access the RAM blocks. All input signals are registered inputs.

### Note

This has the advantage of having the two cycle register-to-register path that accesses the RAM blocks using the same path in memory BIST mode as in functional mode.

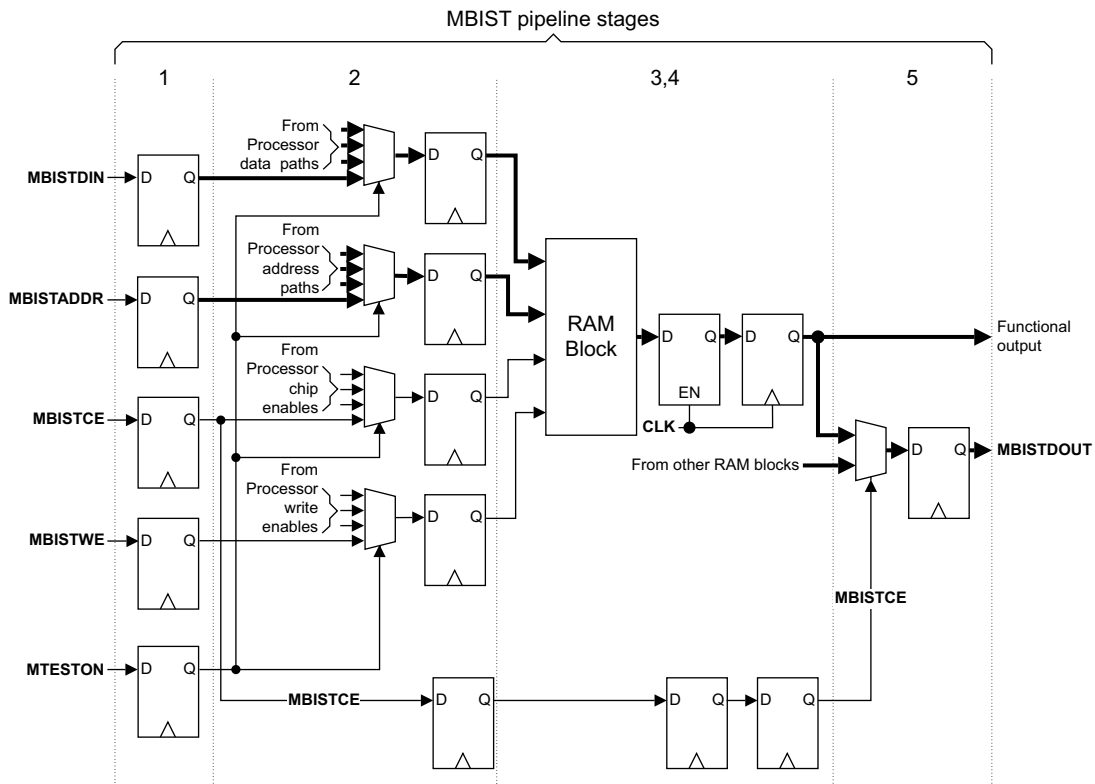

Figure 16-2 Processor Memory BIST interface

Table 16-1 shows the names of the memory BIST interface. The interface has 185 pins.

Table 16-1 Memory BIST interface ports

| Name                        | Direction | Description                                                                                                 |
|-----------------------------|-----------|-------------------------------------------------------------------------------------------------------------|
| MTESTON                     | Input     | Switches multiplexors to give access to the RAM blocks. Must be high during Memory BIST mode.               |
| MBISTDIN[71:0] <sup>a</sup> | Input     | Data to the RAM blocks. Not all RAM blocks use the full width.                                              |
| MBISTADDR[14:0]             | Input     | Address. Not all RAM blocks use the full address width.                                                     |
| MBISTCE[16:0]               | Input     | Chip enables for each of the RAM blocks. Multiple RAM blocks can be selected if output bits do not overlap. |

Table 16-1 Memory BIST interface ports (continued)

| Name                               | Direction | Description                                                                                   |
|------------------------------------|-----------|-----------------------------------------------------------------------------------------------|
| <b>MBISTWE[7:0]</b>                | Input     | Global write enable going to all of the RAM blocks.                                           |
| <b>nMBISTDATARDY</b>               | Output    | Data ready from <i>Data TCM</i> (DTCM) or <i>Instruction TCM</i> (ITCM). Active LOW           |
| <b>MBISTDOUT[71:0]<sup>a</sup></b> | Output    | Data out for all of the RAM blocks. Unused bits of <b>MBISTSDOUT</b> are padded with logic 0. |

a. The bus width is [71:0] regardless of whether parity is implemented or not.

Figure 16-3 shows the pipelining from the MBIST interface, to the memory and back again for a read access. **MBISTCE** selects the RAM block(s). Some RAM blocks might be accessed simultaneously, for example IValidRAM, IValidRAMchk, and DDirtyRAM. In these cases, data from each RAM appears at different locations on the **MBISTDOUT** bus.

#### Note

To enable testing of the RAM blocks in the TCMs you must ensure the error checking logic is bypassed. **DTCTESTEN** and **ITTESTEN** are available for this purpose.

During the test on the RAM block(s) in the TCMs:

- data on **MBISTDOUT** is valid when **nMBISTDATARDY** is LOW
- data is valid on **MBISTDOUT** five cycles after a read is requested through the interface
- signals **DTCTESTEN** and **ITTESTEN** are asserted.

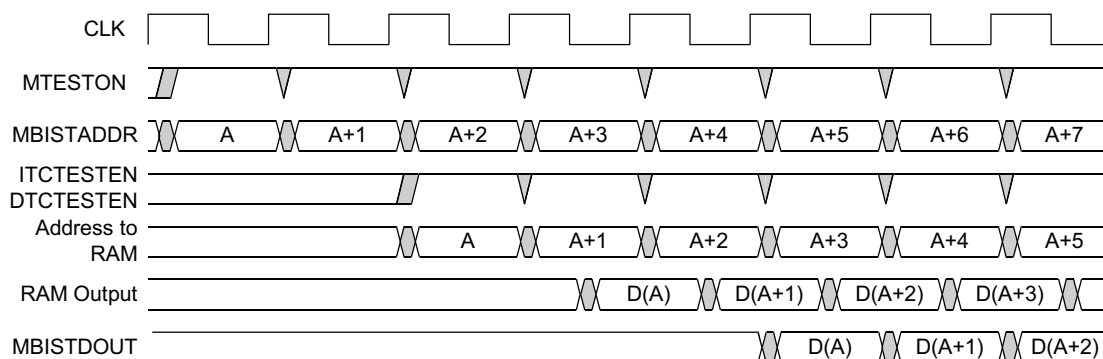

Figure 16-3 Pipelining of the MBIST interface

Table 16-2 to Table 16-6 on page 16-8 show the memory BIST interface signal configurations for accessing RAM blocks.

**Table 16-2 Instruction cache RAM access**

| RAM block             | MBISTCE bit | Data bits      |           | MBISTADDR bits for instruction cache sizes |       |       |       |       |       |        |
|-----------------------|-------------|----------------|-----------|--------------------------------------------|-------|-------|-------|-------|-------|--------|
|                       |             | Parity         | No parity | 1KB                                        | 2KB   | 4KB   | 8KB   | 16KB  | 32KB  | 64KB   |
| IDataRAM3             | 7           | [71:0]         | [63:0]    | -                                          | -     | [6:0] | [7:0] | [8:0] | [9:0] | [10:0] |
| IDataRAM2             | 6           |                |           | -                                          | -     |       |       |       |       |        |
| IDataRAM1             | 5           |                |           | -                                          | [6:0] |       |       |       |       |        |
| IDataRAM0             | 4           |                |           | [6:0]                                      |       |       |       |       |       |        |
| ITagRAM3 <sup>a</sup> | 3           | [52:28]        | [49:28]   | -                                          | -     | [4:0] | [5:0] | [6:0] | [7:0] | [8:0]  |
| ITagRAM1 <sup>a</sup> |             | [24:0]         | [21:0]    | -                                          | -     |       |       |       |       |        |
| ITagRAM2 <sup>a</sup> | 2           | [52:28]        | [49:28]   | -                                          | [4:0] |       |       |       |       |        |
| ITagRAM0 <sup>a</sup> |             | [24:0]         | [21:0]    | [4:0]                                      |       |       |       |       |       |        |
| IValidRAM             | 1           | See Table 16-3 |           | [3:0]                                      | [3:0] | [3:0] | [4:0] | [5:0] | [6:0] | [7:0]  |
| IValidRAMChk          |             |                |           |                                            |       |       |       |       |       |        |

a. See *Tag RAM access* on page 16-9 for more information about ITagRAM read and write accesses.

**Table 16-3 Data bits for variable width instruction cache RAMs**

| RAM block    | Parity or no parity  | Data bits for instruction cache sizes |         |         |         |         |         |         |  |
|--------------|----------------------|---------------------------------------|---------|---------|---------|---------|---------|---------|--|
|              |                      | 1KB                                   | 2KB     | 4KB     | 8KB     | 16KB    | 32KB    | 64KB    |  |
| IValidRAM    | Parity and no parity | [57:56]                               | [59:56] | [63:56] | [63:56] | [63:56] | [63:56] | [63:56] |  |
| IValidRAMChk | Parity               | [65:64]                               | [67:64] | [71:64] | [71:64] | [71:64] | [71:64] | [71:64] |  |
|              | No parity            | -                                     | -       | -       | -       | -       | -       | -       |  |

Table 16-4 Data cache RAM access

| RAM block              | MBISTCE bit | Data bits      |           | MBISTADDR bits for data cache sizes |       |       |       |       |       |        |
|------------------------|-------------|----------------|-----------|-------------------------------------|-------|-------|-------|-------|-------|--------|
|                        |             | Parity         | No parity | 1KB                                 | 2KB   | 4KB   | 8KB   | 16KB  | 32KB  | 64KB   |
| DDataRAM3              | 16          | [71:0]         | [63:0]    | -                                   | -     | [6:0] | [7:0] | [8:0] | [9:0] | [10:0] |
| DDataRAM2              | 15          |                |           | -                                   | -     |       |       |       |       |        |
| DDataRAM1              | 14          |                |           | -                                   | [6:0] |       |       |       |       |        |
| DDataRAM0              | 13          |                |           | [6:0]                               |       |       |       |       |       |        |
| DDTagRAM3a             | 12          | [54:28]        | [51:28]   | -                                   | -     | [4:0] | [5:0] | [6:0] | [7:0] | [8:0]  |
| DDTagRAM1a             |             | [26:0]         | [23:0]    | -                                   | -     |       |       |       |       |        |
| DDTagRAM2 <sup>a</sup> | 11          | [54:28]        | [51:28]   | -                                   | [4:0] |       |       |       |       |        |
| DDTagRAM0 <sup>a</sup> |             | [26:0]         | [23:0]    | [4:0]                               |       |       |       |       |       |        |
| DValidRAM              | 10          | See Table 16-5 |           | [3:0]                               | [3:0] | [3:0] | [4:0] | [5:0] | [6:0] | [7:0]  |
| DValidRAMChk           |             |                |           |                                     |       |       |       |       |       |        |
| DDirtyRAM              | 9           |                |           | [4:0]                               | [4:0] | [4:0] | [5:0] | [6:0] | [7:0] | [8:0]  |
| DDirtyRAMChk           |             |                |           |                                     |       |       |       |       |       |        |

a. See *Tag RAM access* on page 16-9 for more information about DTagRAM read and write accesses.

Table 16-5 Data bits for variable width data cache RAMs

| RAM block    | Parity or no parity  | Data bits for data cache sizes |         |         |         |         |         |         |
|--------------|----------------------|--------------------------------|---------|---------|---------|---------|---------|---------|
|              |                      | 1KB                            | 2KB     | 4KB     | 8KB     | 16KB    | 32KB    | 64KB    |
| DValidRAM    | Parity and no parity | [57:56]                        | [59:56] | [63:56] | [63:56] | [63:56] | [63:56] | [63:56] |
| DValidRAMChk | Parity               | [65:64]                        | [67:64] | [71:64] | [71:64] | [71:64] | [71:64] | [71:64] |
|              | No parity            | -                              | -       | -       | -       | -       | -       | -       |
| DDirtyRAM    | Parity and no parity | [1:0]                          | [3:0]   | [7:0]   | [7:0]   | [7:0]   | [7:0]   | [7:0]   |
| DDirtyRAMChk | Parity               | [9:8]                          | [11:8]  | [15:8]  | [15:8]  | [15:8]  | [15:8]  | [15:8]  |
|              | No parity            | -                              | -       | -       | -       | -       | -       | -       |

Table 16-6 TCM RAM access

| RAM block | MBISTC bit | Data bits |           | MBISTADDR bits for data TCM sizes |       |        |        |        |        |        |
|-----------|------------|-----------|-----------|-----------------------------------|-------|--------|--------|--------|--------|--------|
|           |            | Parity    | No parity | 4KB                               | 8KB   | 16KB   | 32KB   | 64KB   | 128KB  | 256KB  |
| DTCM      | 8          | [71:0]    | [63:0]    | [8:0]                             | [9:0] | [10:0] | [11:0] | [12:0] | [13:0] | [14:0] |
| ITCM      | 0          | [71:0]    | [63:0]    | [8:0]                             | [9:0] | [10:0] | [11:0] | [12:0] | [13:0] | [14:0] |

Table 16-7 shows which RAM block has write enable parity or non parity data bit capability.

Table 16-7 Data bits capability RAM blocks

| RAM block    | Write enable     |                      |
|--------------|------------------|----------------------|
|              | Parity data bits | Non parity data bits |
| IDataRAM3    | Bit              | Byte                 |
| IDataRAM2    |                  |                      |
| IDataRAM1    |                  |                      |
| IDataRAM0    |                  |                      |
| ITagRAM3     | Word             | Word                 |
| ITagRAM1     |                  |                      |

### 16.2.1 Tag RAM access

This section describes memory BIST accesses to TagRAM, for write and read operations. The examples given here describe accesses to ITagRAMs, however the same conditions apply to all memory BIST accesses to ITagRAMs and DTagRAMs.

Table 16-2 on page 16-6 gives more information about ITagRAM accesses, and Table 16-4 on page 16-7 gives similar information about DTagRAM accesses. For accessing the ITagRAMs, Table 16-2 on page 16-6 shows that:

- **MBISTCE[3]** enables ITagRAM3 and ITagRAM1
- **MBISTCE[2]** enables ITagRAM2 and ITagRAM0.

Read and write accesses operate differently, see:

- *Write accesses* on page 16-10
- *Read accesses* on page 16-10.

### Write accesses

When you write to the TagRAMs in memory BIST mode, the same data is driven from the data inputs to both of the enabled TagRAMs. For example, if you perform a memory BIST write with **MBISTCE[3]** set to 1, to enable ITagRAM3 and ITagRAM1:

- with parity, input data bits[24:0] are driven to both ITagRAM3 and ITagRAM1
- with no parity, input data bits[21:0] are driven to both ITagRAM3 and ITagRAM1.

### Read accesses

When you read from the TagRAMs in memory BIST mode, the data from the two TagRAMs is read onto different regions of the data output bus. For example, if you perform a memory BIST read with **MBISTCE[3]** set to 1, to enable ITagRAM3 and ITagRAM1:

- with parity:
  - data from ITagRAM3 is read onto data output bits[52:28]
  - data from ITagRAM1 is read onto data output bits[24:0]
- with no parity:
  - data from ITagRAM3 is read onto data output bits[49:28]
  - data from ITagRAM1 is read onto data output bits[21:0].

## 16.2.2 ARM Memory BIST Controller

You can use the memory BIST interface described in this chapter with the ARM memory BIST controller. This provides the ability to test all of the RAM blocks in the processor using a variety of algorithms.

The ARM memory BIST controller does not support the use of **nMBISTDATARDY**. It cannot test variable latency RAM blocks that require the use of **nITCDATARDY** and **nDTCDATARDY**.

## 16.2.3 Third party tool support

If a third-party tool is used to create a memory BIST controller, instead of using the memory BIST controller supplied, you must be aware that:

- A five-stage pipeline is required to access the RAM blocks.

- Except for a few cases, you must access RAM blocks individually. Only RAM blocks without common data bits can be accessed at the same time. Also you can test the Cache Valid RAM blocks in conjunction with the Cache Tag RAM blocks (see Table 16-2 on page 16-6 and Table 16-4 on page 16-7).
- The entire MBISTDOUT interface is not always used. Only valid data bits must be compared by the chosen memory BIST controller.

## 16.3 Power-On Test

The requirements for power-on-test include the ability to detect that the major functional units are working at power-on. This includes the ability of testing the L1 memory under software control.

For the data cache a suitable test program is required that exercises all locations. CP15 operations are included to enable the data cache Tag and Valid RAM blocks to be initialized under software control.

For the instruction cache, it is necessary to initialize the cache contents with a test program using CP15 operations. The test program then enables reads from the cache to take place at a rate close to that of a normal application.

For more details, see *Cache debug and software test access* on page 3-9.

You can also use the Memory BIST ports to initialize the cache memories. In this mode the controller behaves like a DMA controller and initializes all memory locations. during this preload time you must ensure the core is not functional. You might have to reset the core after the preload.

For testing the Instruction and Data TCMs, similar methods can be used, whereby a test program and test data are loaded into the relevant TCM. When initialized the processor can switch to executing code from the Instruction TCM, with its data space within the Data TCM. No additional access features are required for TCM testing as both TCMs are accessible by the processor for data accesses.

## 16.4 Running System Test

Running system test can make use of similar methods as the power-on test. The current contents of the registers, cache and TCM memories can be stored into memory outside of the macrocell, and test code loaded into the cache in its place. At the completion of the test sequence the storage within the processor might be re-instated to the pretest values and normal operation resumed.

It is expected that run-time test is initiated by software, and that the data cache is cleaned before the test data is loaded into the cache.

# Chapter 17

## Cycle Timings and Interlock Behavior

This chapter describes the cycle timings and interlock behavior of integer instructions on the ARM1156T2F-S processor. This chapter contains the following sections:

- *About cycle timings and interlock behavior* on page 17-3
- *Register interlock examples* on page 17-8
- *Data processing instructions* on page 17-9
- *QADD, QDADD, QSUB, and QDSUB instructions* on page 17-12
- *ARMv6 media data-processing* on page 17-13
- *ARMv6 Sum of Absolute Differences* on page 17-15
- *Multiplies* on page 17-16
- *Branches* on page 17-18
- *Processor state updating instructions* on page 17-19
- *Single load and store instructions* on page 17-20
- *Load and Store Doubleword instructions* on page 17-23
- *Load and Store Multiple instructions* on page 17-25
- *RFE and SRS instructions* on page 17-28
- *Synchronization instructions* on page 17-29.
- *Coprocessor instructions* on page 17-30
- *SVC, BKPT, undefined, and prefetch aborted instructions* on page 17-31

- *CBZ, CBNZ, and IT instructions* on page 17-32
- *Bitfield instructions* on page 17-33
- *NOP (CPS) instruction* on page 17-34
- *Table branch instructions* on page 17-35.

## 17.1 About cycle timings and interlock behavior

Complex instruction dependencies and memory system interactions make it impossible to describe briefly the exact cycle timing behavior for all instructions in all circumstances. The timings described in this chapter are accurate in most cases. If precise timings are required you must use a cycle-accurate model of the ARM1156T2F-S processor.

Unless stated otherwise cycle counts and result latencies described in this chapter are best case numbers. They assume:

- no outstanding data dependencies between the current instruction and a previous instruction
- the instruction does not encounter any resource conflicts
- all data accesses hit in the data cache, and do not cross protection region boundaries
- all instruction accesses hit in the instruction cache.

This section contains:

- *Instruction execution overview*
- *Conditional instructions* on page 17-4
- *Opposite condition code checks* on page 17-5
- *Definition of terms* on page 17-6
- *Instruction sets* on page 17-7.

### 17.1.1 Instruction execution overview

The instruction execution pipeline is constructed from three parallel four-stage pipelines, see Table 17-1. For a complete description of these pipeline stages see *Pipeline stages* on page 1-23.

**Table 17-1 Pipeline stages**

| Pipeline   | Stages |      |      |      |
|------------|--------|------|------|------|
| ALU        | Sh     | ALU  | Sat  | WBex |
| Multiply   | MAC1   | MAC2 | MAC3 | -    |
| Load/Store | ADD    | DC1  | DC2  | WBls |

The ALU and multiply pipelines operate in a lock-step manner, causing all instructions in these pipelines to retire in order. The load/store pipeline is a decoupled pipeline enabling subsequent instructions in the ALU and multiply pipeline to complete underneath outstanding loads.

Extensive forwarding to the Sh, MAC1, ADD, ALU, MAC2, and DC1 stages enables many dependent instruction sequences to run without pipeline stalls. General forwarding occurs from the ALU, Sat, WBex and WBls pipeline stages. In addition, the multiplier contains an internal multiply accumulate forwarding path.

Most instructions do not require a register until the ALU stage. All result latencies are given as the number of cycles until the register is required by a following instruction in the ALU stage. The following sequence takes four cycles:

```
LDR R1, [R2] ;Result latency three
ADD R3, R3, R1 ;Register R1 required by ALU
```

If a subsequent instruction requires the register at the start of the Sh, MAC1, or ADD stage then an extra cycle must be added to the result latency of the instruction producing the required register. Instructions that require a register at the start of these stages are specified by describing that register as an Early register. The following sequence, requiring an Early register, takes five cycles:

```
LDR R1, [R2] ;Result latency three plus one
ADD R3, R3, R1 LSL#6 ;plus one because Register R1 is required by Sh
```

Finally, some instructions do not require a register until their second execution cycle. If a register is not required until the ALU, MAC2, or DC1 stage for the second execution cycle, then a cycle can be subtracted from the result latency for the instruction producing the required register. If a register is not required until this later point, it is specified as a Late register. The following sequence where R1 is a Late register takes four cycles:

```
LDR R1, [R2] ;Result latency three minus one
ADD R3,R1,R3,LSLR4 ;minus one because Register R1 is a Late register
 ;This ADD is a two issue cycle instruction
```

## 17.1.2 Conditional instructions

Most instructions execute in one or two cycles. If these instructions fail their condition codes then they take one and two cycles respectively.

Multiplies, MSR, and some CP14 and CP15 coprocessor instructions are the only instructions that require more than two cycles to execute. If one of these instructions fails its condition codes, then it takes a variable number of cycles to execute. The number of cycles is dependent on:

- the length of the operation
- the number of cycles between the setting of the flags and the start of the dependent instruction.

The worst-case number of cycles for a condition code failing multicycle instruction is five.

The following algorithm describes the number of cycles taken for a multi-cycle instruction that fails its condition-code:

$\text{Min}(\text{NonFailingCycleCount}, \text{Max}(5 - \text{FlagCycleDistance}, 3))$

Where:

**Max (a, b)** returns the maximum of the two values a, b.

**Min (a, b)** returns the minimum of the two values a, b.

**NonFailingCycleCount**

is the number of cycles that the failing instruction would have taken had it passed.

**FlagCycDistance**

is the number of cycles between the instruction that sets the flags and the conditional instruction, including interlocking cycles. For example:

- The following sequence has a FlagCycleDistance of 0 because the instructions are back-to-back with no interlocks:  

```

ADDS R1, R2, R3
MULEQ R4, R5, R6

```
- The following sequence has a FlagCycleDistance of one:  

```

ADDS R1, R2, R3
MOV R0, R0
MULEQ R4, R5, R6

```

### 17.1.3 Opposite condition code checks

If instruction A and instruction B both write the same register the pipeline must ensure that the register is written in the correct order. Therefore, interlocks might be required to correctly resolve this pipeline hazard.

The only useful sequences where two instructions write the same register without an instruction reading its value in between are when the two instructions have opposite sets of condition codes. The ARM1156T2F-S processor optimizes these sequences to prevent unnecessary interlocks. For example:

- The following sequences take two cycles to execute:

```
ADDNE R1, R5, R6
LDREQ R1, [R8]

LDREQ R1, [R8]
ADDNE R1, R5, R6
```
- The following sequence also takes two cycles to execute, because the STR instruction does not store the value of R1 produced by the QDADDNE instruction:

```
QDADDNE R1, R5, R6
STREQ R1, [R8]
```

17.1.4 Definition of terms

Table 17-2 gives descriptions of cycle timing terms used in this chapter.

Table 17-2 Definition of cycle timing terms

| Term                  | Description                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cycles                | This is the minimum number of cycles required by an instruction.                                                                                                                                                                                                                                                                                                                |
| Result latency        | This is the number of cycles before the result of this instruction is available for a following instruction requiring the result at the start of the ALU, MAC2, and DC1 stage. This is the normal case. Exceptions to this mark the register as an Early register. <div><div>Note</div>The result latency is the number of cycles from the first cycle of an instruction.</div> |
| Register lock latency | Applies to STM and STRD instructions only. This is the number of cycles that a register is write-locked for by this instruction, preventing subsequent instructions that want to write the register from starting. This lock is required to prevent a following instruction from writing to a register before it has been read.                                                 |
| Early register        | The specified register is required at the start of the Sh, MAC1, and ADD stage. For interlock calculations add one cycle to the result latency of the instruction producing this register.                                                                                                                                                                                      |
| Late register         | The specified register is not required until the start of the ALU, MAC2, and DC1 stage for the second execution. For interlock calculations subtract one cycle from the result latency of the instruction producing this register.                                                                                                                                              |
| FlagsCycleDistance    | The number of cycles between an instruction that sets the flags and the conditional instruction.                                                                                                                                                                                                                                                                                |

### 17.1.5 Instruction sets

For any equivalent instruction, the cycle timing behavior is always the same whether it is an ARM, Thumb or Thumb-2 instruction.

———— **Note** —————

Instructions from all instruction sets are listed, but some instructions and some register combinations or addressing modes might not be available in all instruction sets.

---

## 17.2 Register interlock examples

Table 17-3 shows register interlock examples using LDR and ADD instructions.

LDR instructions take one cycle, have a result latency of three, and require their base register as an Early register.

ADD instructions take one cycle and have a result latency of one.

**Table 17-3 Register interlock examples**

| Instruction sequence             | Behavior                                                                                             |
|----------------------------------|------------------------------------------------------------------------------------------------------|
| LDR R1, [R2]<br>ADD R6, R5, R4   | Takes two cycles because there are no register dependencies                                          |
| ADD R1, R2, R3<br>ADD R9, R6, R1 | Takes two cycles because ADD instructions have a result latency of one                               |
| LDR R1, [R2]<br>ADD R6, R5, R1   | Takes four cycles because of the result latency of R1                                                |
| ADD R2, R5, R6<br>LDR R1, [R2]   | Takes three cycles because of the use of the result of R2 as an Early register                       |
| LDR R1, [R2]<br>LDR R5, [R1]     | Takes five cycles because of the result latency and the use of the result of R1 as an Early register |

## 17.3 Data processing instructions

This section describes the cycle timing behavior for the ADDW, MOVt, MOVW, SUBW, EOR, SUB, RSB, ADD, ADC, SBC, RSC, CMN, ORR, MOV, BIC, MVN, TST, TEQ, CMP, and CLZ instructions.

### 17.3.1 Cycle counts if destination is not PC

Table 17-4 shows the cycle timing behavior for data processing instructions if its destination is not the PC. You can substitute ADD with any of the data processing instructions identified in the opening paragraph of this section.

**Table 17-4 Data processing instruction cycle timing behavior if destination is not PC**

| Example instruction                | Cycles | Early register | Late register | Result latency | Comment                             |
|------------------------------------|--------|----------------|---------------|----------------|-------------------------------------|
| ADD <Rd>, <Rn>, <Rm>               | 1      | -              | -             | 1              | Normal case.                        |
| ADD <Rd>, <Rn>, <Rm>, LSL #<immed> | 1      | <Rm>           | -             | 1              | Requires a shifted source register. |
| ADD <Rd>, <Rn>, <Rm>, LSL <Rs>     | 2      | <Rs>           | <Rn>          | 2              | See footnote <sup>a</sup> .         |
| ADDW <Rd>, <Rm>, #<imm12>          | 1      | -              | -             | 1              | -                                   |
| MOVW <Rd>, #<imm16>                | 1      | -              | -             | 1              | -                                   |

- a. Requires a register controlled shifted source register. Instruction takes two issue cycles. In the first cycle the shift distance Rs is sampled. In the second cycle the actual shift of Rm and the ADD instruction occurs.

### 17.3.2 Cycle counts if destination is the PC

Table 17-5 on page 17-10 shows the cycle timing behavior for data processing instructions if its destination is the PC. You can substitute ADD with any data processing instruction except for a MOV or a CLZ. A CLZ with the PC as the destination is an Unpredictable instruction.

The timings for a MOV instruction are given separately in the table.

For condition code failing cycle counts, the cycles for the non-PC destination variants must be used.

**Table 17-5 Data processing instruction cycle timing behavior if destination is the PC**

| Example instruction                     | Cycles           | Early register | Late register | Result latency | Comment                                                       |
|-----------------------------------------|------------------|----------------|---------------|----------------|---------------------------------------------------------------|
| MOV pc, 1r                              | 1                | -              | -             | -              | Correctly return stack predicted MOV pc, 1r                   |
| MOV pc, 1r                              | 8                | -              | -             | -              | Incorrectly return stack predicted MOV pc, 1r                 |
| MOV <cond> pc, 1r                       | 6-8 <sup>a</sup> | -              | -             | -              | Conditional return, or return when return stack is empty      |
| MOV pc, <Rd>                            | 6                | -              | -             | -              | MOV to PC, no shift required                                  |
| MOV <cond> pc, <Rd>                     | 6-8 <sup>a</sup> | -              | -             | -              | Conditional MOV to PC, no shift required                      |
| MOV pc, <Rn>, <Rm>, LSL #<immed>        | 7                | <Rm>           | -             | -              | Conditional MOV to PC, with a shifted source register         |
| MOV <cond> pc, <Rn>, <Rm>, LSL #<immed> | 7-8 <sup>a</sup> | -              | -             | -              | Conditional MOV to PC, with a shifted source register         |
| MOV pc, <Rn>, <Rm>, LSL <Rs>            | 8                | <Rs>           | <Rn>          | -              | MOV to pc, with a register controlled shifted source register |
| ADD pc, <Rd>, <Rm>                      | 8                | -              | -             | -              | Normal case to PC                                             |
| ADD pc, <Rn>, <Rm>, LSL #<immed>        | 8                | <Rm>           | -             | -              | Requires a shifted source register                            |
| ADD pc, <Rn>, <Rm>, LSL <Rs>            | 9                | <Rs>           | <Rn>          | -              | Requires a register controlled shifted source register        |

a. If the instruction is conditional and passes conditional checks it takes MAX(MaxCycles - FlagCycleDistance, MinCycles), If the instruction is unconditional it takes Min Cycles.

### 17.3.3 Example interlocks

Most data processing instructions are single-cycle and can be executed back-to-back without interlock cycles, even if there are data dependencies between them. The exceptions to this are when the Shifter or Register controlled shifts are used.

#### Shifter

The shifter is in a separate pipeline stage from the ALU. A register required by the shifter is an Early register and requires an additional cycle of result availability before use. For example, the following sequence introduces a one-cycle interlock, and takes three cycles to execute:

```
ADD R1,R2,R3
ADD R4,R5,R1 LSL #1
```

The second source register, which is not shifted, does not incur an extra data dependency check. Therefore, the following sequence takes two cycles to execute:

```
ADD R1,R2,R3
ADD R4,R1,R9 LSL #1
```

#### Register controlled shifts

Register controlled shifts take two cycles to execute:

- the register containing the shift distance is read in the first cycle
- the shift is performed in the second cycle
- The final operand is not required until the ALU stage for the second cycle.

Because a shift distance is required, the register containing the shift distance is an Early register and incurs an extra interlock penalty. For example, the following sequence takes four cycles to execute:

```
ADD R1, R2, R3
ADD R4, R2, R4, LSL R1
```

RRX requires the Carry Flag early.

## 17.4 QADD, QDADD, QSUB, and QDSUB instructions

This section describes the cycle timing behavior for the QADD, QDADD, QSUB, and QDSUB instructions.

These instructions perform saturating arithmetic. Their result is produced during the Sat stage, consequently they have a result latency of two. The QDADD and QDSUB instructions must double and saturate the register <Rn> before the addition. This operation occurs in the Sh stage of the pipeline, consequently this register is an Early register.

Table 17-6 shows the cycle timing behavior for QADD, QDADD, QSUB, and QDSUB instructions.

**Table 17-6 QADD, QDADD, QSUB, and QDSUB instruction cycle timing behavior**

| Instructions | Cycles | Early register | Result latency |
|--------------|--------|----------------|----------------|
| QADD, QSUB   | 1      | -              | 2              |
| QDADD, QDSUB | 1      | <Rn>           | 2              |

## 17.5 ARMv6 media data-processing

Table 17-7 shows ARMv6 media data-processing instructions and gives their cycle timing behavior.

All ARMv6 media data-processing instructions are single-cycle issue instructions. These instructions produce their results in either the ALU or Sat stage, and have result latencies of one or two accordingly. Some of the instructions require an input register to be shifted before use and therefore are marked as requiring an Early register.

**Table 17-7 ARMv6 media data-processing instructions cycle timing behavior**

| Instructions                     | Cycles | Early register | Result latency |
|----------------------------------|--------|----------------|----------------|
| SADD16, SSUB16, SADD8, SSUB8     | 1      | -              | 1              |
| UADD16, USUB16, UADD8, USUB8     | 1      | -              | 1              |
| SEL                              | 1      | -              | 1              |
| QADD16, QSUB16, QADD8, QSUB8     | 1      | -              | 2              |
| SHADD16, SHSUB16, SHADD8, SHSUB8 | 1      | -              | 2              |
| UQADD16, UQSUB16, UQADD8, UQSUB8 | 1      | -              | 2              |
| UHADD16, UHSUB16, UHADD8, UHSUB8 | 1      | -              | 2              |
| SSAT16, USAT16                   | 1      | -              | 2              |
| SASX, SSAX                       | 1      | <Rm>           | 1              |
| UASX, USAX                       | 1      | <Rm>           | 1              |
| SXTAB16, SXTAB, SXTAH            | 1      | <Rm>           | 1              |
| SXTB16, SXTB, SXTB               | 1      | <Rm>           | 1              |
| UXTB16, UXTB, UXTB               | 1      | <Rm>           | 1              |
| UXTAB16, UXTAB, UXTAH            | 1      | <Rm>           | 1              |
| REV, REV16, REVSH, RBIT          | 1      | <Rm>           | 1              |
| PKHBT, PKHTB                     | 1      | <Rm>           | 1              |
| SSAT, USAT                       | 1      | <Rm>           | 2              |
| QASX, QSAX                       | 1      | <Rm>           | 2              |

**Table 17-7 ARMv6 media data-processing instructions cycle timing behavior**

| Instructions | Cycles | Early register | Result latency |
|--------------|--------|----------------|----------------|
| SHASX, SHSAX | 1      | <Rm>           | 2              |
| UQASX, UQSAX | 1      | <Rm>           | 2              |
| UHASX, UHSAX | 1      | <Rm>           | 2              |

## 17.6 ARMv6 Sum of Absolute Differences

Table 17-8 shows ARMv6 *Sum of Absolute Differences* (SAD) instructions and gives their cycle timing behavior.

**Table 17-8 ARMv6 SAD instruction timing behavior**

| Instructions | Cycles | Early register | Result latency |
|--------------|--------|----------------|----------------|
| USAD8        | 1      | <Rm>, <Rs>     | 3 <sup>a</sup> |
| USADA8       | 1      | <Rm>, <Rs>     | 3              |

a. Result latency is one less If the destination is the accumulate for a subsequent USADA8.

### 17.6.1 Example interlocks

Table 17-9 shows interlock examples using USAD8 and USADA8 instructions.

**Table 17-9 Example interlocks**

| Instruction sequence                                     | Behavior                                                                                                                             |
|----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| USAD8 R1,R2,R3<br>ADD R5,R6,R1                           | Takes four cycles because USAD8 has a Result latency of three, and the ADD requires the result of the USAD8 instruction.             |
| USAD8 R1,R2,R3<br>MOV R9,R9<br>MOV R9,R9<br>ADD R5,R6,R1 | Takes four cycles. The MOV instructions are scheduled during the Result latency of the USAD8 instruction.                            |
| USAD8 R1,R2,R3<br>USADA8 R1,R4,R5,R1                     | Takes three cycles. The Result latency is one less because the result is used as the accumulate for a subsequent USADA8 instruction. |

## 17.7 Multiplies

The multiplier consists of a three-cycle pipeline with early result forwarding not possible other than to the internal accumulate path. For a subsequent multiply accumulate the result is available one cycle earlier than for all other uses of the result.

Certain multiplies require:

- more than one cycle to execute.
- more than one pipeline issue to produce a result.

Multiplies with 64-bit results take and require two cycles to write the results, consequently they have two result latencies with the low half of the result always available first. The multiplicand and multiplier are required as Early registers because they are both required at the start of MAC1.

Table 17-10 shows the cycle timing behavior of example multiply instructions.

**Table 17-10 Example multiply instruction cycle timing behavior**

| Example instruction | Cycles | Cycles if sets flags | Early register | Late register | Result latency |
|---------------------|--------|----------------------|----------------|---------------|----------------|
| MUL(S)              | 2      | 5                    | <Rm>, <Rs>     | -             | 4              |
| MLA(S), MLS         | 2      | 5                    | <Rm>, <Rs>     | <Rn>          | 4              |
| SMULL(S)            | 3      | 6                    | <Rm>, <Rs>     | -             | 4/5            |
| UMULL(S)            | 3      | 6                    | <Rm>, <Rs>     | -             | 4/5            |
| SMLAL(S)            | 3      | 6                    | <Rm>, <Rs>     | <RdLo>        | 4/5            |
| UMLAL(S)            | 3      | 6                    | <Rm>, <Rs>     | <RdLo>        | 4/5            |
| SMULxy              | 1      | -                    | <Rm>, <Rs>     | -             | 3              |
| SMLAxy              | 1      | -                    | <Rm>, <Rs>     | -             | 3              |
| SMULWy              | 1      | -                    | <Rm>, <Rs>     | -             | 3              |
| SMLAWy              | 1      | -                    | <Rm>, <Rs>     | -             | 3              |
| SMLALxy             | 2      | -                    | <Rm>, <Rs>     | <RdHi>        | 3/4            |
| SMUAD, SMUADX       | 1      | -                    | <Rm>, <Rs>     | -             | 3              |
| SMLAD, SMLADX       | 1      | -                    | <Rm>, <Rs>     | -             | 3              |
| SMUSD, SMUSDx       | 1      | -                    | <Rm>, <Rs>     | -             | 3              |
| SMLSD, SMLSDx       | 1      | -                    | <Rm>, <Rs>     | -             | 3              |

**Table 17-10 Example multiply instruction cycle timing behavior (continued)**

| Example instruction | Cycles | Cycles if sets flags | Early register | Late register | Result latency |
|---------------------|--------|----------------------|----------------|---------------|----------------|
| SMMUL, SMMULR       | 2      | -                    | <Rm>, <Rs>     | -             | 4              |
| SMMLA, SMMLAR       | 2      | -                    | <Rm>, <Rs>     | <Rn>          | 4              |
| SMMLS, SMMLSR       | 2      | -                    | <Rm>, <Rs>     | <Rn>          | 4              |
| SMLALD, SMLALDX     | 2      | -                    | <Rm>, <Rs>     | <RdHi>        | 3/4            |
| SMLSLD, SMLSLDX     | 2      | -                    | <Rm>, <Rs>     | <RdHi>        | 3/4            |
| UMAAL               | 3      | -                    | <Rm>, <Rs>     | <RdLo>        | 4/5            |

**Note**

Result latency is one less if the result is used as the accumulate register for a subsequent multiply accumulate.

## 17.8 Branches

This section describes the cycle timing behavior for the B, BL, and BLX instructions.

Branches are subject to dynamic and return stack predictions. Table 17-11 shows example branch instructions and their cycle timing behavior.

Table 17-11 Branch instruction cycle timing behavior

| Example instruction               | Cycles           | Comment                           |
|-----------------------------------|------------------|-----------------------------------|
| B <immed>                         | 0                | Folded dynamic prediction         |
| B<immed>, BL<immed>, BLX<immed>   | 1                | Not-folded dynamic prediction     |
| B<immed>, BL<immed>, BLX<immed>   | 6-8 <sup>a</sup> | Incorrect dynamic prediction      |
| BX R14                            | 1                | Correct return stack prediction   |
| BX R14                            | 8                | Incorrect return stack prediction |
| BX R14                            | 6                | Empty return stack                |
| BX <cond> R14                     | 6-8 <sup>a</sup> | Conditional return                |
| BX <cond> <reg>, BLX <cond> <reg> | 1                | If not taken                      |
| BX <cond> <reg>, BLX <cond> <reg> | 6-8 <sup>a</sup> | If taken                          |

a. Mispredicted branches, including taken unpredicted branches, takes a varying number of cycles to execute depending on their distance from a flag setting instruction. The timing behavior is:  
Cycle = MAX(MaxCycles - FlagCycleDistance, MinCycles).

## 17.9 Processor state updating instructions

This section describes the cycle timing behavior for the MSR, MRS, CPS, and SETEND instructions. Table 17-12 shows processor state updating instructions and their cycle timing behavior.

**Table 17-12 Processor state updating instructions cycle timing behavior**

| instruction                    | Cycles | Comments                               |
|--------------------------------|--------|----------------------------------------|
| MRS                            | 1      | All MRS instructions                   |
| MSR CPSR_f                     | 1      | MSR to CPSR flags only                 |
| MSR                            | 4      | All other MSR instructions to the CPSR |
| MSR SPSR                       | 5      | All MSR instructions to the SPSR       |
| CPS <effect> <iflags>          | 1      | Interrupt masks only                   |
| CPS <effect> <iflags>, #<mode> | 2      | Mode changing                          |
| SETEND                         | 1      | -                                      |

17.10 Single load and store instructions

This section describes the cycle timing behavior for LDR, LDRHT, LDRSBT, LDRSHT, LDRT, LDRB, LDRBT, LDRSB, LDRH, LDRSH, STR, STRT, STRB, STRBT, STRH, and PLD instructions.

Table 17-13 shows the cycle timing behavior for stores and loads, other than loads to the PC. You can replace LDR with any of the above single load or store instructions. The following rules apply:

- They are single-cycle issue if a constant offset is used or if a register offset with no shift, or shift by 2 is used. Both the base and any offset register are Early registers.
- They are two-cycle issue if either a negative register offset or a shift other than LSL #2 is used. Only the offset register is an Early register.
- If ARMv6 unaligned support is enabled then accesses to addresses not aligned to the access size generates two memory accesses, and so consume the load/store unit for an additional cycle. This extra cycle is required if the base or the offset is not aligned to the access size, consequently the final address is potentially unaligned, even if the final address turns out to be aligned.
- If ARMv6 unaligned support is enabled and the final access address is unaligned there is an extra cycle of result latency.
- Because a PLD instruction is handled as any other load instruction by all levels of cache, the PLD instruction follows standard data-dependency rules and eviction procedures. During any stage of PLD execution, the PLD instruction is ignored in case of an address translation fault, a cache hit, or an abort.  
Only use the PLD instruction to preload from cacheable Normal memory.
- The updated base register has a result latency of one. For back-to-back load/store instructions with base write back, the updated base is available to the following load/store instruction with a result latency of 0.

Table 17-13 Cycle timing behavior for stores and loads, other than loads to the PC

| Example instruction                     | Cycles | Memory cycles | Result latency | Comments                                  |
|-----------------------------------------|--------|---------------|----------------|-------------------------------------------|
| LDR <Rd>, <addr_md_1cyc1e> <sup>a</sup> | 1      | 1             | 3              | Pre-ARMv6 access, or ARMv6 aligned access |

| LDR <Rd>, <addr_md_2cycle> <sup>a</sup> | 2      | 3             | 5              | ARMv6 unaligned access             |

a. See Table 17-15 on page 17-22 for an explanation of <addr\_md\_1cycle> and <addr\_md\_2cycle>.

Table 17-14 shows the cycle timing behavior for loads to the PC.

**Table 17-14 Cycle timing behavior for loads to the PC**

| Example instruction                   | Cycles | Memory cycles | Result latency | Comments                                  |
|---------------------------------------|--------|---------------|----------------|-------------------------------------------|
| LDR pc, [sp, #cns] (!)                | 4      | 1             | -              | Correctly return stack predicted          |
| LDR pc, [sp], #cns                    | 4      | 1             | -              | Correctly return stack predicted          |
| LDR pc, [sp, #cns] (!)                | 10     | 1             | -              | Return stack mispredicted                 |
| LDR pc, [sp], #cns                    | 10     | 1             | -              | Return stack mispredicted                 |
| LDR <cond> pc, [sp, #cns] (!)         | 9      | 1             | -              | Conditional return, or empty return stack |
| LDR <cond> pc, [sp], #cns             | 9      | 1             | -              | Conditional return, or empty return stack |
| LDR pc, <addr_md_1cycle> <sup>a</sup> | 9      | 1             | -              | -                                         |
| LDR pc, <addr_md_2cycle> <sup>a</sup> | 10     | 2             | -              | -                                         |

a. See Table 17-15 on page 17-22 for an explanation of <addr\_md\_1cycle> and <addr\_md\_2cycle>.

Only cycle times for aligned accesses are given because Unaligned accesses to the PC are not supported.

ARM1156T2F-S processor includes a three-entry return stack that can predict procedure returns. Any load to the PC with an immediate offset, and the stack pointer R13 as the base register is considered a procedure return.

For condition code failing cycle counts, you must use the cycles for the non-PC destination variants.

Table 17-15 shows the explanation of <addr\_md\_1cycle> and <addr\_md\_2cycle> used in Table 17-13 on page 17-20 and Table 17-14 on page 17-21.

17.10.1 Base register update

The base register update for load or store instructions occurs in the ALU pipeline. To prevent an interlock for back-to-back load or store instructions reusing the same base register, there is a local forwarding path to recycle the updated base register around the ADD stage.

For example, the following instruction sequence take three cycles to execute:

```
LDR R5, [R2, #4]!
LDR R6, [R2, #0x10]!
LDR R7, [R2, #0x20]!
```

## 17.11 Load and Store Doubleword instructions

This section describes the cycle timing behavior for the LDRD and STRD instructions

The LDRD and STRD instructions:

- Are two-cycle issue if either a negative register offset or a shift other than LSL #2 is used. Only the offset register is an Early register.
- Are single-cycle issue if either a constant offset is used or if a register offset with no shift, or shift by 2 is used. Both the base and any offset register are Early registers.
- Take only one memory cycle if the address is doubleword aligned.
- Take two memory cycles if the address is not doubleword aligned.

The updated base register has a result latency of one. For back-to-back load/store instructions with base write back, the updated base is available to the following load/store instruction with a result latency of 0.

To prevent instructions after a STRD from writing to a register before it has stored that register, the STRD registers have a lock latency that determines how many cycles it is before a subsequent instruction which writes to that register can start.

Table 17-16 shows the cycle timing behavior for LDRD and STRD instructions.

**Table 17-16 Load and Store Doubleword instructions cycle timing behavior**

| Example instruction                             | Cycles | Memory cycles | Result latency for LDRD | Register lock latency for STRD | Instruction set |
|-------------------------------------------------|--------|---------------|-------------------------|--------------------------------|-----------------|
| <b>Address is doubleword aligned</b>            |        |               |                         |                                |                 |
| LDRD <Rt>, <Rt2>, <addr_md_1cycle> <sup>a</sup> | 1      | 1             | 3/3                     | 1,2                            | ARM and Thumb-2 |
| LDRD <Rt>, <Rt2>, <addr_md_2cycle> <sup>a</sup> | 2      | 2             | 4/4                     | 2,3                            |                 |
| <b>Address not doubleword aligned</b>           |        |               |                         |                                |                 |
| LDRD <Rt>, <Rt2>, <addr_md_1cycle> <sup>a</sup> | 1      | 2             | 3/4                     | 1,2                            | ARM             |
|                                                 |        |               | 4/4                     | 2,2                            | Thumb-2         |
| LDRD <Rt>, <Rt2>, <addr_md_2cycle> <sup>a</sup> | 2      | 3             | 4/5                     | 2,3                            | ARM             |
|                                                 |        |               | 5/5                     | 3,3                            | Thumb-2         |

a. See Table 17-17 on page 17-24 for an explanation of <addr\_md\_1cycle> and <addr\_md\_2cycle>.

Table 17-17 shows the explanation of <addr\_md\_1cycle> and <addr\_md\_2cycle> used in Table 17-16 on page 17-23.

## 17.12 Load and Store Multiple instructions

This section describes the cycle timing behavior for the LDM and STM instructions.

These instructions take one cycle to issue but then use multiple memory cycles to load/store all the registers. Because the memory datapath is 64-bits wide, two registers can be loaded or stored on each cycle. Following non-dependent, non-memory instructions can execute in the integer pipeline while these instructions complete. A dependent instruction is one that either:

- writes a register that has not yet been stored
- reads a register that has not yet been loaded.

Before a load or store multiple can begin all the registers in the register list must be available. For example, a STM cannot begin until all outstanding loads for registers in the register list have completed.

To prevent instructions after a store multiple from writing to a register before a store multiple has stored that register, the register list has a lock latency that determines how many cycles it is before a subsequent instruction which writes to that register can start.

### 17.12.1 Load and Store Multiples, other than Load Multiples including the PC

In all cases the base register, Rx, is an Early register.

Table 17-18 shows the cycle timing behavior of load and store multiples including the PC.

**Table 17-18 Cycle timing behavior of Load and Store Multiples, other than load multiples including the PC**

| Example instruction                  | Cycles | Memory cycles | Result latency for LDM | Register lock latency for STM |
|--------------------------------------|--------|---------------|------------------------|-------------------------------|
| <b>First address 64-bit aligned</b>  |        |               |                        |                               |
| LDM Rx, {R1}                         | 1      | 1             | 3                      | 1                             |
| LDM Rx, {R1, R2}                     | 1      | 1             | 3, 3                   | 1, 2                          |
| LDM Rx, {R1, R2, R3}                 | 1      | 2             | 3, 3, 4                | 1, 2, 2                       |
| LDM Rx, {R1, R2, R3, R4}             | 1      | 2             | 3, 3, 4, 4             | 1, 2, 2, 3                    |
| LDM Rx, {R1, R2, R3, R4, R5}         | 1      | 3             | 3, 3, 4, 4, 5          | 1, 2, 2, 3, 3                 |
| LDM Rx, {R1, R2, R3, R4, R5, R6}     | 1      | 3             | 3, 3, 4, 4, 5, 5       | 1, 2, 2, 3, 3, 4              |
| LDM Rx, {R1, R2, R3, R4, R5, R6, R7} | 1      | 4             | 3, 3, 4, 4, 5, 5, 6    | 1, 2, 2, 3, 3, 4, 4           |

**Table 17-18 Cycle timing behavior of Load and Store Multiples, other than load multiples including the PC (continued)**

| Example instruction                     | Cycles | Memory cycles | Result latency for LDM | Register lock latency for STM |
|-----------------------------------------|--------|---------------|------------------------|-------------------------------|
| <b>First address not 64-bit aligned</b> |        |               |                        |                               |
| LDM Rx, {R1}                            | 1      | 1             | 3                      | 1                             |
| LDM Rx, {R1,R2}                         | 1      | 2             | 3, 4                   | 1, 2                          |
| LDM Rx, {R1,R2,R3}                      | 1      | 2             | 3, 4, 4                | 1, 2, 2                       |
| LDM Rx, {R1,R2,R3,R4}                   | 1      | 3             | 3, 4, 4, 5             | 1, 2, 2, 3                    |
| LDM Rx, {R1,R2,R3,R4,R5}                | 1      | 3             | 3, 4, 4, 5, 5          | 1, 2, 2, 3, 4                 |
| LDM Rx, {R1,R2,R3,R4,R5,R6}             | 1      | 4             | 3, 4, 4, 5, 5, 6       | 1, 2, 2, 3, 4, 4              |
| LDM Rx, {R1,R2,R3,R4,R5,R6,R7}          | 1      | 4             | 3, 4, 4, 5, 5, 6, 6    | 1, 2, 2, 3, 4, 4, 5           |

**17.12.2 Load Multiples, where the PC is in the register list**

If a LDM loads the PC then the PC access is performed first to accelerate the branch, followed by the rest of the register loads. The cycle timings and all register load latencies for LDMs with the PC in the list are one greater than the cycle times for the same LDM without the PC in the list.

ARM1156T2F-S processor includes a three-entry return stack which can predict procedure returns. Any LDM to the PC with the stack point (R13) as the base register, and which does not restore the SPSR to the CPSR, is predicted as a procedure return.

For condition code failing cycle counts, the cycles for the non-PC destination variants must be used. These are all single-cycle issue, consequently a condition code failing LDM to the PC takes one cycle.

In all cases the base register, Rx, is an Early register, and requires an extra cycle of result latency to provide its value.

Table 17-19 shows the cycle timing behavior of Load Multiples, where the PC is in the register list.

**Table 17-19 Cycle timing behavior of Load Multiples, where the PC is in the register list**

| Example instruction     | Cycles | Memory cycles <sup>a</sup> | Result latency | Comments                                  |
|-------------------------|--------|----------------------------|----------------|-------------------------------------------|
| LDM sp!,{...,pc}        | 4      | 1+n                        | 4, ...         | Correctly return stack predicted          |
| LDM sp!,{...,pc}        | 10     | 1+n                        | 4, ...         | Return stack mispredicted                 |
| LDM <cond> sp!,{...,pc} | 9      | 1+n                        | 4, ...         | Conditional return, or empty return stack |
| LDM Rx,{...,pc}         | 10     | 1+n                        | 4, ...         | Not return stack predicted                |

a. Where n is the number of memory cycles for this instruction if the PC had not been in the register list.

### 17.12.3 Example Interlocks

The following sequence that has an LDM instruction take five cycles, because R3 has a result latency of four cycles:

```
LDM R0, {R1-R7}
ADD R10, R10, R3
```

The following that has an STM instruction takes five cycles to execute, because R6 has a register lock latency of four cycles:

```
STMIA R0, {R1-R7}
ADD R6, R10, R11
```

### 17.13 RFE and SRS instructions

This section describes the cycle timing for the RFE and SRS instructions.

These instructions return from an exception and save exception return state respectively. The RFE instruction always requires two memory cycles. It first loads the SPSR value from the stack, and then the return address. The SRS instruction takes one or two memory cycles depending on doubleword alignment first address location.

In all cases the base register is an Early register, and requires an extra cycle of result latency to provide its value.

Table 17-20 shows the cycle timing behavior for RFE and SRS instructions.

**Table 17-20 RFE and SRS instructions cycle timing behavior**

| Example instruction            | Cycles | Memory cycles |
|--------------------------------|--------|---------------|
| Address doubleword aligned     |        |               |
| RFEIA <Rn>                     | 10     | 2             |
| SRSIA #<mode>                  | 1      | 1             |
| Address not doubleword aligned |        |               |
| RFEIA <Rn>                     | 10     | 2             |
| SRSIA #<mode>                  | 1      | 2             |

## 17.14 Synchronization instructions

This section describes the cycle timing behavior for the SWP, SWPB, LDREX, and STREX instructions

In all cases the base register, Rn, is an Early register, and requires an extra cycle of result latency to provide its value. Table 17-21 shows the synchronization instructions cycle timing behavior.

**Table 17-21 Synchronization instructions cycle timing behavior**

| Instruction             | Cycles | Memory cycles | Result latency |
|-------------------------|--------|---------------|----------------|
| SWP <Rd>, <Rm>, [Rn]    | 2      | 2             | 3              |
| SWPB <Rd>, <Rm>, [Rn]   | 2      | 2             | 3              |
| LDREX <Rd>, [Rn]        | 1      | 1             | 3              |
| STREX, <Rd>, <Rm>, [Rn] | 1      | 1             | 3              |

## 17.15 Coprocessor instructions

This section describes the cycle timing behavior for the CDP, LDC, STC, LDCL, STCL, MCR, MRC, MCRR, and MRRC instructions.

The precise timing of coprocessor instructions is tightly linked with the behavior of the relevant coprocessor. For LDC and STC instructions, the coprocessor can determine how many words are required. Table 17-22 shows the coprocessor instructions cycle timing behavior. The numbers shown in Table 17-22 are best case numbers.

**Table 17-22 Coprocessor instructions cycle timing behavior**

| Instruction | Cycles | Memory cycles | Result latency |
|-------------|--------|---------------|----------------|
| MCR         | 1      | 1             | -              |
| MCRR        | 1      | 1             | -              |
| MRC         | 1      | 1             | 3              |
| MRRC        | 1      | 1             | 3/3            |
| LDC, LDCL   | 1      | As required   | -              |
| STC, STCL   | 1      | As required   | -              |
| CDP         | 1      | 1             | -              |

## 17.16 SVC, BKPT, undefined, and prefetch aborted instructions

This section describes the cycle timing behavior for SVC and BKPT, and for instructions that generate an Undefined Instruction or Prefetch Abort exception.

In all cases the exception is taken in the WBex stage of the pipeline. SVC and most undefined instructions that fail their condition codes take one cycle. A small number of undefined instructions that fail their condition codes take two cycles. Table 17-23 shows the SVC, BKPT, undefined, and prefetch aborted instruction cycle timing behavior.

**Table 17-23 SVC, BKPT, undefined, prefetch aborted instructions cycle timing behavior**

| Instruction           | Cycles |
|-----------------------|--------|
| SVC                   | 9      |
| BKPT                  | 9      |
| Prefetch Abort        | 9      |
| Undefined Instruction | 9      |

17.17 CBZ, CBNZ, and IT instructions

This section describes the cycle timing behavior for the CBZ, CBNZ, and IT instructions. Table 17-24 shows instruction cycle timing behavior for these instructions.

Table 17-24 CBZ and IT instructions cycle timing behavior

| Example instructions     | Cycles | Early register | Late register | Result latency | Comment               |
|--------------------------|--------|----------------|---------------|----------------|-----------------------|
| CBZ <Rn>, <label>        | 1      | -              | -             | -              | Correctly predicted   |
|                          | 8      | -              | -             | -              | Incorrectly predicted |
| CBNZ <Rn>, <label>       | 1      | -              | -             | -              | Correctly predicted   |
|                          | 8      | -              | -             | -              | Incorrectly predicted |
| IT{<v>{<w>{<z>}}} <cond> | 1      | -              | -             | -              | -                     |
|                          | 0      | -              | -             | -              | If folded out         |

## 17.18 Bitfield instructions

This section describes the cycle timing behavior for the BFC, BFI, SBFX, and UBFX instructions. Table 17-25 shows the bitfield instruction cycle timing behavior.

**Table 17-25 Thumb-2 bitfield instruction cycle timing behavior**

| Example instructions                                                                 | Cycles | Early register | Late register | Result latency | Comment |
|--------------------------------------------------------------------------------------|--------|----------------|---------------|----------------|---------|
| SBFX <cond> <Rd>, <Rm>, #<lsb>, #<width><br>UBFX <cond> <Rd>, <Rn>, #<lsb>, #<width> | 1      | <Rm>           | -             | 1              | -       |
| BFI <cond> <Rd>, <Rn>, #<lsb>, #<width><br>BFC <cond> <Rd>, #<lsb>, #<width>         | 2      | <Rn>, <Rd>     | -             | 2              | -       |

17.19 NOP (CPS) instruction

This section describes the cycle timing behavior for the NOP (CPS) instruction.  
Table 17-26 shows the NOP (CPS) instruction cycle timing behavior.

Table 17-26 Thumb-2 NOP (CPS) instruction cycle timing behavior

| instruction | Cycles | Early register | Late register | Result latency | Comment |
|-------------|--------|----------------|---------------|----------------|---------|
| NOP         | 1      | -              | -             | -              | -       |

## 17.20 Table branch instructions

This section describes the cycle timing behavior for the TBB and TBH instructions. Table 17-27 shows the table branch instructions cycle timing behavior.

**Table 17-27 Thumb-2 table branch instructions cycle timing behavior**

| Example instructions                    | Cycles | Comment |
|-----------------------------------------|--------|---------|
| TBB <Rd>, <addr_md_1cycle> <sup>a</sup> | 10     | -       |
| TBH <Rd>, <addr_md_2cycle> <sup>a</sup> | 11     | -       |

a. See Table 17-15 on page 17-22 for an explanation of <addr\_md\_1cycle> and <addr\_md\_2cycle>.

# Chapter 18

## AC Characteristics

This chapter gives the timing parameters for the ARM1156T2F-S processor. This chapter contains the following sections:

- *ARM1156T2F-S timing diagrams* on page 18-2
- *ARM1156T2F-S timing parameters* on page 18-3.

## 18.1 ARM1156T2F-S timing diagrams

The AMBA bus interface of the ARM1156T2F-S processor conforms to the *AMBA Specification*. For the relevant timing diagrams, see the *AMBA Specification*.

## 18.2 ARM1156T2F-S timing parameters

This section describes the input and output port timing parameters for the ARM1156T2F-S processor.

The maximum timing parameter or constraint delay for each ARM1156T2F-S processor signal applied to the SoC is given as a percentage in Table 18-1 to Table 18-9 on page 18-8. The input and output delay columns provide the maximum and minimum time as a percentage of the ARM1156T2F-S processor clock cycle given to the SoC for that signal.

### 18.2.1 Input port timing parameters

Table 18-1 shows AXI bus interface input port timing parameters.

**Table 18-1 AXI bus interface input port timing parameters:**

| Input delay Min.  | Input delay Max. | Signal name          |
|-------------------|------------------|----------------------|
| Clock uncertainty | 40%              | <b>ACLKENRW</b>      |
| Clock uncertainty | 50%              | <b>ARREADYRW</b>     |
| Clock uncertainty | 50%              | <b>AWREADYRW</b>     |
| Clock uncertainty | 50%              | <b>WREADYRW</b>      |
| Clock uncertainty | 50%              | <b>BVALIDRW</b>      |
| Clock uncertainty | 50%              | <b>RVALIDRW</b>      |
| Clock uncertainty | 70%              | <b>RLASTRW</b>       |
| Clock uncertainty | 70%              | <b>BRESPRW[1:0]</b>  |
| Clock uncertainty | 70%              | <b>RRESPRW[1:0]</b>  |
| Clock uncertainty | 70%              | <b>RDATARW[63:0]</b> |
| Clock uncertainty | 40%              | <b>ACLKENI</b>       |
| Clock uncertainty | 50%              | <b>ARREADYI</b>      |
| Clock uncertainty | 50%              | <b>AWREADYI</b>      |
| Clock uncertainty | 50%              | <b>WREADYI</b>       |
| Clock uncertainty | 50%              | <b>BVALIDI</b>       |
| Clock uncertainty | 50%              | <b>RVALIDI</b>       |

**Table 18-1 AXI bus interface input port timing parameters: (continued)**

| <b>Input delay Min.</b> | <b>Input delay Max.</b> | <b>Signal name</b>  |
|-------------------------|-------------------------|---------------------|
| Clock uncertainty       | 70%                     | <b>RLASTI</b>       |
| Clock uncertainty       | 70%                     | <b>BRESPI[1:0]</b>  |
| Clock uncertainty       | 70%                     | <b>RRESPI[1:0]</b>  |
| Clock uncertainty       | 70%                     | <b>RDATAI[63:0]</b> |
| Clock uncertainty       | 40%                     | <b>ACLKENP</b>      |
| Clock uncertainty       | 50%                     | <b>ARREADYP</b>     |
| Clock uncertainty       | 50%                     | <b>AWREADYP</b>     |
| Clock uncertainty       | 50%                     | <b>WREADYP</b>      |
| Clock uncertainty       | 50%                     | <b>BVALIDP</b>      |
| Clock uncertainty       | 50%                     | <b>RVALIDP</b>      |
| Clock uncertainty       | 70%                     | <b>BRESPP[1:0]</b>  |
| Clock uncertainty       | 70%                     | <b>RRESPP[1:0]</b>  |
| Clock uncertainty       | 70%                     | <b>RDATAP[63:0]</b> |

Table 18-2 shows TCM interface port timing parameters.

**Table 18-2 TCM interface port timing parameters**

| <b>Input delay Min.</b> | <b>Input delay Max.</b> | <b>Signal name</b>       |
|-------------------------|-------------------------|--------------------------|
| Clock uncertainty       | 40%                     | <b>DTCDATAOUT[63:0]</b>  |
| Clock uncertainty       | 40%                     | <b>DTCDATAERROR[7:0]</b> |

# Chapter 19

## VFP Introduction

This chapter introduces the VFP11 coprocessor. It contains the following sections:

- *About the VFP11 coprocessor* on page 19-2
- *Applications* on page 19-3
- *Coprocessor interface* on page 19-4
- *VFP11 coprocessor pipelines* on page 19-5
- *Modes of operation* on page 19-12
- *Short vector instructions* on page 19-15
- *Parallel execution of instructions* on page 19-16
- *VFP11 treatment of branch instructions* on page 19-17
- *Writing optimal VFP11 code* on page 19-18
- *VFP11 revision information* on page 19-19.

## 19.1 About the VFP11 coprocessor

The VFP11 coprocessor is an implementation of the *ARM Vector Floating-point Architecture* (VFPv2). It provides low-cost floating-point computation that is fully compliant with the *ANSI/IEEE Std 754-1985, IEEE Standard for Binary Floating-Point Arithmetic*, referred to in this document as the IEEE 754 standard. The VFP11 coprocessor supports all addressing modes described in the *ARM Architecture Reference Manual*.

The VFP11 coprocessor is optimized for:

- high data transfer bandwidth through 64-bit split load and store buses
- fast hardware execution of a high percentage of operations on normalized data, resulting in higher overall performance while providing full IEEE 754 standard support when required
- hardware divide and square root operations in parallel with other arithmetic operations to reduce the impact of long-latency operations
- near IEEE 754 standard compatibility in RunFast mode without support code assistance, providing determinable run-time calculations for all input data
- low power consumption, small die size, and reduced kernel code.

The VFP11 coprocessor is an ARM enhanced numeric coprocessor that provides IEEE 754 standard-compatible operations. Designed for the ARM11 family of cores, the VFP11 coprocessor fully supports single-precision and double-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. Conversions between floating-point data formats and ARM integer word format are provided, with special operations to perform the conversion in round-towards-zero mode for high-level language support.

The VFP11 coprocessor provides a performance-power-area solution for embedded applications and high performance for general-purpose applications.

———— **Note** ————

This manual describes only VFP11-specific implementation issues. For more information on the Vector Floating-point Architecture, see the *ARM Architecture Reference Manual*.

---

## 19.2 Applications

The VFP11 coprocessor provides floating-point computation suitable for a wide spectrum of applications such as:

- personal digital assistants and smartphones for graphics, voice compression and decompression, user interfaces, Java interpretation, and *Just In Time* (JIT) compilation
- games machines for three-dimensional graphics and digital audio
- printers and *MultiFunction Peripheral* (MFP) controllers for high-definition color rendering
- set-top boxes for digital audio and digital video, and three-dimensional user interfaces
- automotive applications for engine management and power train computations.

## 19.3 Coprocessor interface

The VFP11 coprocessor is integrated with an ARM11 processor through a dedicated VFP coprocessor interface.

The VFP11 coprocessor uses coprocessor ID number 10 for single-precision instructions and coprocessor ID number 11 for double-precision instructions. In some cases, such as mixed-precision instructions, the coprocessor ID represents the destination precision. In a system containing a VFP11 coprocessor, these coprocessor ID numbers must not be used by another coprocessor.

Access to the VFP11 coprocessor is controlled by the ARM11 Coprocessor Access Control Register. The coprocessor access rights must be configured correctly before any VFP11 instructions can be executed. For more details, see *c1, Coprocessor Access Control Register* on page 3-53.

## 19.4 VFP11 coprocessor pipelines

The VFP11 coprocessor has three separate instruction pipelines:

- the *Multiply and Accumulate* (FMAC) pipeline
- the *Divide and Square root* (DS) pipeline
- the *Load/Store* (LS) pipeline.

Each pipeline can operate independently of the other pipelines and in parallel with them. Each of the three pipelines shares the first two pipeline stages, Decode and Issue. These two stages and the first cycle of the Execute stage of each pipeline remain in lockstep with the ARM11 pipeline stage but effectively one cycle behind the ARM11 pipeline. When the ARM11 processor is in the Issue stage for a particular VFP instruction, the VFP11 coprocessor is in the Decode stage for the same instruction. This lockstep mechanism maintains in-order issue of instructions between the ARM11 processor and the VFP11 coprocessor.

The three pipelines can operate in parallel, enabling more than one instruction to be completed per cycle. Instructions issued to the FMAC pipeline can complete out of order with respect to operations in the LS and DS pipelines. This out-of-order completion might be visible to the user when a short vector FMAC or DS operation generates an exception, and an LS operation begins before the exception is detected. The destination registers or memory of the LS operation reflect the completion of a transfer. The destination registers of the exceptional FMAC or DS operation retain the values they had before the operation started. This is described in more detail in *Parallel execution* on page 22-23.

Except for divide and square root operations, the pipelines support single-cycle throughput for all single-precision operations and most double-precision operations. Double-precision multiply and multiply and accumulate operations have a two-cycle throughput. The LS pipeline is capable of supplying two single-precision operands or one double-precision operand per cycle, balancing the data transfer capability with the operand requirements.

### 19.4.1 FMAC pipeline

Figure 19-1 on page 19-6 shows the structure of the FMAC pipeline.

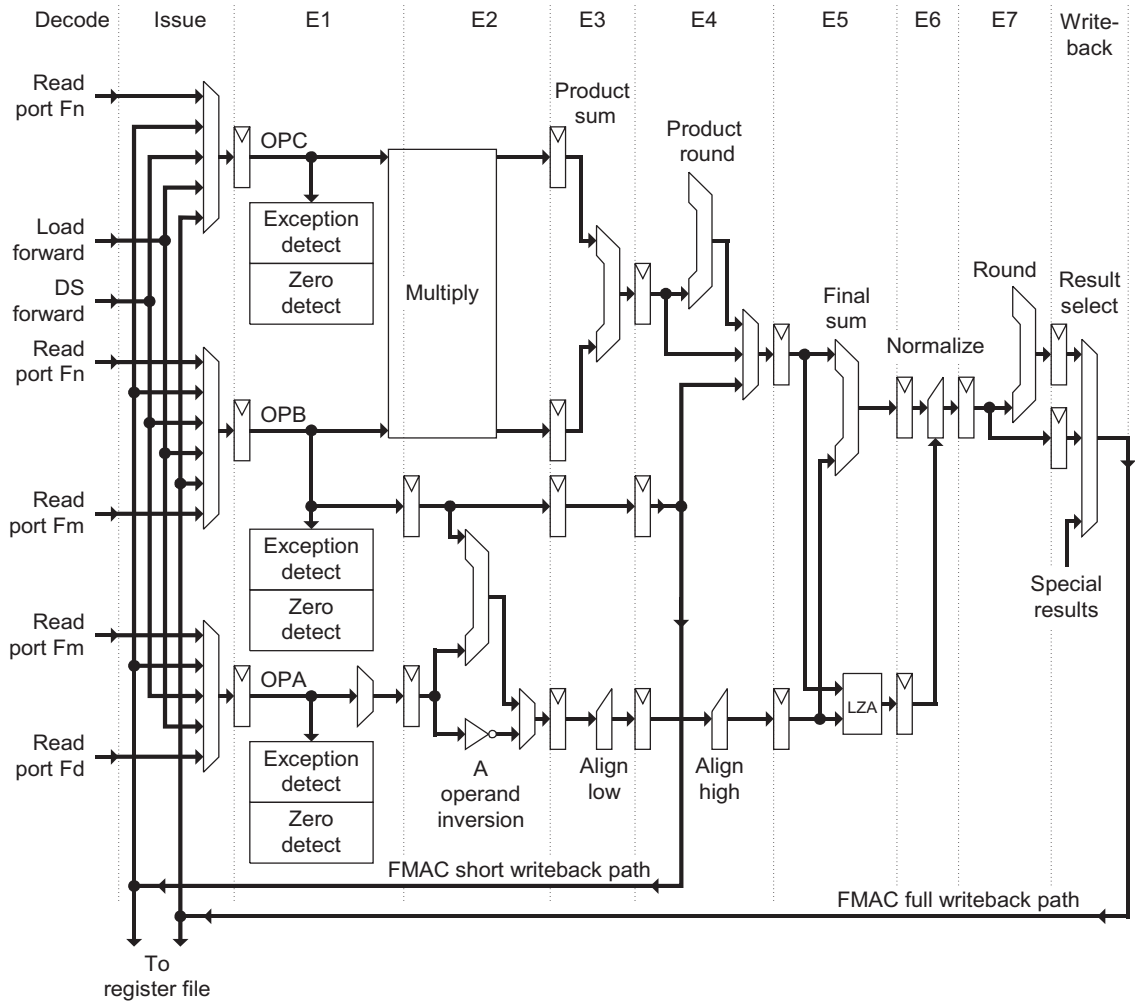

Figure 19-1 FMAC pipeline

### FMAC pipeline instructions

The FMAC pipeline executes the following instructions:

|              |                   |
|--------------|-------------------|
| <b>FADD</b>  | Add.              |
| <b>FSUB</b>  | Subtract.         |
| <b>FMUL</b>  | Multiply.         |
| <b>FNMUL</b> | Negated multiply. |

|               |                                                                        |
|---------------|------------------------------------------------------------------------|
| <b>FMAC</b>   | Multiply and accumulate.                                               |
| <b>FNMAC</b>  | Negated multiply and accumulate.                                       |
| <b>FMSC</b>   | Multiply and subtract.                                                 |
| <b>FNMSC</b>  | Negated multiply and subtract.                                         |
| <b>FABS</b>   | Absolute value.                                                        |
| <b>FNEG</b>   | Negation.                                                              |
| <b>FUITO</b>  | Convert unsigned integer to float.                                     |
| <b>FTOUI</b>  | Convert float to unsigned integer.                                     |
| <b>FSITO</b>  | Convert signed integer to float.                                       |
| <b>FTOSI</b>  | Convert float to signed integer.                                       |
| <b>FTOUIZ</b> | Convert float to unsigned integer with forced round-towards-zero mode. |
| <b>FTOSIZ</b> | Convert float to signed integer with forced round-towards-zero mode.   |
| <b>FCMP</b>   | Compare.                                                               |
| <b>FCMPE</b>  | Compare (NaN exceptions).                                              |
| <b>FCMPZ</b>  | Compare with zero.                                                     |
| <b>FCMPEZ</b> | Compare with zero (NaN exceptions).                                    |
| <b>FCVTSD</b> | Convert from double-precision to single-precision.                     |
| <b>FCVTDS</b> | Convert from single-precision to double-precision.                     |
| <b>FCPY</b>   | Copy register.                                                         |

See *Execution timing* on page 22-25 for cycle counts.

The FMAC family of instructions (FMAC, FNMAC, FMSC, and FNMSC) perform a chained multiply and accumulate operation. The product is computed, rounded according to the specified rounding mode and destination precision, and checked for exceptions before the accumulate operation is performed. The accumulate operation is also rounded according to the specified rounding mode and destination precision and checked for exceptions. The final result is identical to the equivalent sequence of operations executed in sequence. Exception processing and status reporting also reflect the independence of the components of the chained operations.

As an example, the FMAC instruction performs a chained multiply and add operation with the following sequence of operations:

1. The product of the operands in the Fn and Fm registers is computed.
2. The product is rounded according to the current rounding mode and destination precision and checked for exceptions.
3. The result is summed with the operand in the Fd register.

4. The sum is rounded according to the current rounding mode and destination precision and checked for exceptions. If no exception conditions that require support code are present, the result is written to the Fd register.

For example, the following two operations return the same result:

```
FMACS S0, S1, S2
```

```
FMULS TEMP, S1, S2
```

```
FADDS S0, S0, TEMP
```

## 19.4.2 DS pipeline

Figure 19-2 shows the structure of the DS pipeline.

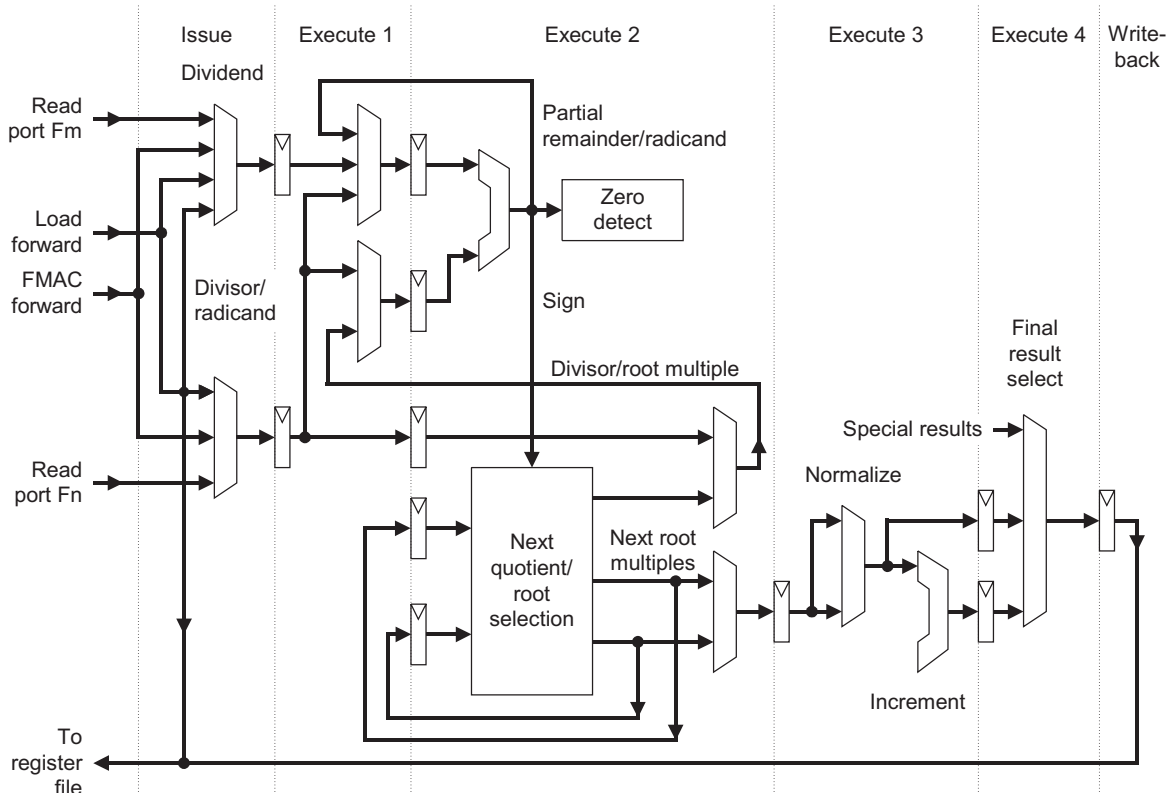

Figure 19-2 DS pipeline

## DS pipeline instructions

The DS pipeline executes the following instructions:

**FDIV**          Divide.

**FSQRT**        Square root.

The VFP11 coprocessor executes divide and square root instructions for both single-precision and double-precision operands with all IEEE 754 standard rounding modes supported. The DS unit uses a shared radix-4 algorithm that provides a good balance between speed and chip area. DS operations have a latency of 19 cycles for single-precision operations and 33 cycles for double-precision operations. The throughput is 15 cycles for single-precision operations and 29 cycles for double-precision operations.

### 19.4.3 LS pipeline

The LS pipeline handles all of the instructions that involve data transfer to and from the ARM11 processor, including loads, stores, moves to coprocessor system registers, and moves from coprocessor system registers. It remains synchronized with the ARM11 LS pipeline for the duration of the instruction.

Data written to the ARM11 processor is read from the VFP11 coprocessor register file in the Issue stage and transferred to the ARM11 processor in the next cycle and is latched on the ARM11 data cache1/data cache 2 cycle boundary. The transfer is made on a dedicated 64-bit store data bus between the VFP11 coprocessor and the ARM11 processor.

Load data is written to the VFP11 coprocessor on a dedicated 64-bit load bus between the ARM11 processor and all coprocessors. Data is received by the VFP11 coprocessor in the Writeback stage. Data is written to the register file in the Writeback stage, and available for forwarding to data processing operations in the same cycle. Figure 19-3 on page 19-10 shows the structure of the LS pipeline.

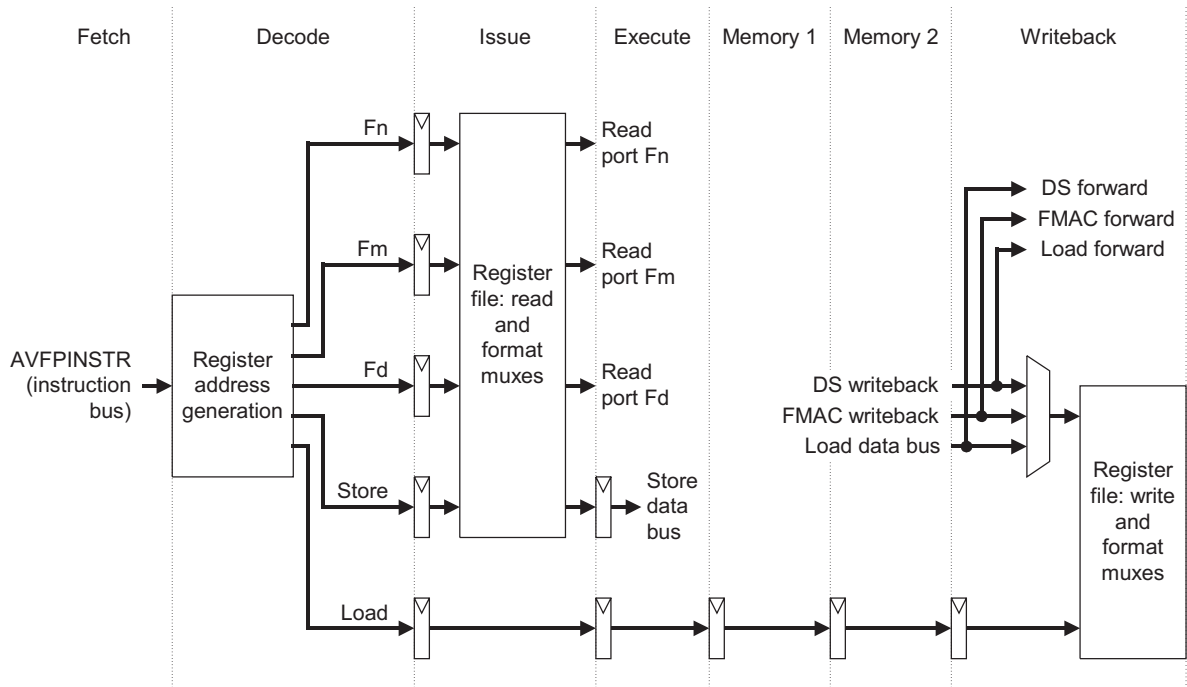

Figure 19-3 LS pipeline

### LS pipeline instructions

The LS pipeline executes the following instructions:

- |             |                                                                                                                         |
|-------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>FLD</b>  | Load a single-precision, double-precision, or 32-bit integer value from memory to the VFP11 register file.              |
| <b>FLDM</b> | Load up to 32 single-precision or integer values or 16 double-precision values from memory to the VFP11 register file.  |
| <b>FST</b>  | Store a single-precision, double-precision, or 32-bit integer value from the VFP11 register file to memory.             |
| <b>FSTM</b> | Store up to 32 single-precision or integer values or 16 double-precision values from the VFP11 register file to memory. |
| <b>FMSR</b> | Move a single-precision or integer value from an ARM11 register to a VFP11 single-precision register.                   |

|               |                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------|
| <b>FMRS</b>   | Move a single-precision or integer value from a VFP11 single-precision register to an ARM11 register.        |
| <b>FMDHR</b>  | Move an ARM11 register value to the upper half of a VFP11 double-precision register.                         |
| <b>FMDLR</b>  | Move an ARM11 register value to the lower half of a VFP11 double-precision register.                         |
| <b>FMRDH</b>  | Move the upper half of a double-precision value from a VFP11 double-precision register to an ARM11 register. |
| <b>FMRDL</b>  | Move the lower half of a double-precision value from a VFP11 double-precision register to an ARM11 register. |
| <b>FMDRR</b>  | Move two ARM11 register values to a VFP11 double-precision register.                                         |
| <b>FMRRD</b>  | Move a double-precision VFP11 register value to two ARM11 registers.                                         |
| <b>FMSRR</b>  | Move two ARM11 register values to two consecutively-numbered VFP11 single-precision registers.               |
| <b>FMRRS</b>  | Move two consecutively-numbered VFP11 single-precision register values to two ARM11 registers.               |
| <b>FMXR</b>   | Move an ARM11 register value to a VFP11 control register.                                                    |
| <b>FMRX</b>   | Move a VFP11 control register value to an ARM11 register.                                                    |
| <b>FMSTAT</b> | Move N, C, Z, and V flags from the VFP11 FPSCR to the ARM11 CPSR.                                            |

## 19.5 Modes of operation

The VFP11 coprocessor provides full IEEE 754 standard compatibility through a combination of hardware and software. There are rare cases that require significant additional compute time to resolve correctly according to the requirements of the IEEE 754 standard. For instance, the VFP11 coprocessor does not process subnormal input values directly. To provide correct handling of subnormal inputs according to the IEEE 754 standard, a trap is made to support code to process the operation. Using the support code for processing this operation can require hundreds of cycles. In some applications this is unavoidable, because compliance with the IEEE 754 standard is essential to proper operation of the program. In many other applications, strict compliance to the IEEE 754 standard is unnecessary, while determinable runtime, low interrupt latency, and low power are of more importance. To accommodate a variety of applications, the VFP11 coprocessor provides four modes of operation:

- *Full-compliance mode*
- *Flush-to-zero mode* on page 19-13
- *Default NaN mode* on page 19-13
- *RunFast mode* on page 19-13.

### 19.5.1 Full-compliance mode

When the VFP11 coprocessor is in full-compliance mode, all operations that cannot be processed according to the IEEE 754 standard use support code for assistance. The operations requiring support code are:

- Any CDP operation involving a subnormal input when not in flush-to-zero mode. Enable flush-to-zero mode by setting the FZ bit, FPSCR[24].
- Any CDP operation involving a NaN input when not in default NaN mode. Enable default NaN mode by setting the DN bit, FPSCR[25].
- Any CDP operation that has the potential of generating an underflow condition when not in flush-to-zero mode.
- Any CDP operation when Inexact exceptions are enabled. Enable Inexact exceptions by setting the IXE bit, FPSCR[12].
- Any CDP operation that can cause an overflow while Overflow exceptions are enabled. Enable Overflow exceptions by setting the OFE bit, FPSCR[10].
- Any CDP operation that involves an invalid arithmetic operation or an arithmetic operation on a signaling NaN when Invalid Operation exceptions are enabled. Enable Invalid Operation exceptions by setting the IOE bit, FPSCR[8].

- A float-to-integer conversion that has the potential to create an integer that cannot be represented in the destination integer format when Invalid Operation exceptions are enabled.

The support code:

- determines the nature of the exception
- determines if processing is required to perform the computation
- calls a function to compute the result and status
- transfers control to the user trap handler if the enable bit is set for a detected exception
- writes the result to the destination register, updates the FPSCR register, and returns to the user code if no enabled exception is detected
- passes control to the user trap handler and supplies any specified intermediate result for the exception if an enabled exception is detected.

*Arithmetic exceptions* on page 23-25 describes the conditions under which the VFP11 coprocessor traps to support code.

### 19.5.2 Flush-to-zero mode

Setting the FZ bit, FPSCR[24], enables flush-to-zero mode and increases performance on very small inputs and results. In flush-to-zero mode, the VFP11 coprocessor treats all subnormal input operands of arithmetic CDP operations as positive zeros in the operation. Exceptions that result from a zero operand are signaled appropriately. FABS, FNEG, FCPY, and FCMP are not considered arithmetic CDP operations and are not affected by flush-to-zero mode. A result that is *tiny*, as described in the IEEE 754 standard, for the destination precision is smaller in magnitude than the minimum normal value *before rounding* and is replaced with a positive zero. The IDC flag, FPSCR[7], indicates when an input flush occurs. The UFC flag, FPSCR[3], indicates when a result flush occurs.

### 19.5.3 Default NaN mode

Setting the DN bit, FPSCR[25], enables default NaN mode. In default NaN mode, the result of any operation that involves an input NaN or generated a NaN result returns the default NaN. Propagation of the fraction bits is maintained only by FABS, FNEG, and FCPY operations, all other CDP operations ignore any information in the fraction bits of an input NaN. See *NaN handling* on page 21-5 for a description of default NaNs.

### 19.5.4 RunFast mode

RunFast mode is the combination of the following conditions:

- the VFP11 coprocessor is in flush-to-zero mode

- the VFP11 coprocessor is in default NaN mode
- all exception enable bits are cleared.

In RunFast mode the VFP11 coprocessor:

- processes subnormal input operands as positive zeros
- processes results that are tiny before rounding, that is, between the positive and negative minimum normal values for the destination precision, as positive zeros
- processes input NaNs as default NaNs
- returns the default result specified by the IEEE 754 standard for overflow, division by zero, invalid operation, or inexact operation conditions fully in hardware and without additional latency
- processes all operations in hardware without trapping to support code.

RunFast mode enables the programmer to write code for the VFP11 coprocessor that runs in a determinable time without support code assistance, regardless of the characteristics of the input data. In RunFast mode, no user exception traps are available. However, the exception flags in the FPSCR register are compliant with the IEEE 754 standard for Inexact, Overflow, Invalid Operation, and Division by Zero exceptions. The underflow flag is modified for flush-to-zero mode. Each of these flags is set by an exceptional condition and can be cleared only by a write to the FPSCR register.

## 19.6 Short vector instructions

The VFPv2 architecture supports execution of *short vector* instructions of up to eight operations on single-precision data and up to four operations on double-precision data. Short vectors are most useful in graphics and signal-processing applications. They reduce code size, increase speed of execution by supporting parallel operations and multiple transfers, and simplify algorithms with high data throughput.

Short vector operations issue the individual operations specified in the instruction in a serial fashion. To eliminate data hazards, short vector operations begin execution only after all source registers are available, and all destination registers are not targets of other operations.

See Chapter 22 *VFP Instruction Execution* for more information on execution of short vector instructions.

## 19.7 Parallel execution of instructions

The VFP11 coprocessor provides the ability to execute several floating-point operations in parallel, while the ARM11 processor is executing ARM instructions. While a short vector operation executes for a number of cycles in the VFP11 coprocessor, it appears to the ARM11 processor as a single-cycle instruction and is retired in the ARM11 processor before it completes execution in the VFP11 coprocessor.

The three pipelines are designed to operate independently of one another once initial processing is completed. This makes it possible to issue a short vector operation and a load or store multiple operation in the next cycle and have both executing at the same time, provided no data hazards exist between the two instructions. With this mechanism, algorithms that can be double-buffered can be written to hide much of the time to transfer data to and from the VFP11 coprocessor under the arithmetic operations, resulting in a significant improvement in performance.

The separate DS pipeline enables both data transfer operations and CDPs that are not to the DS pipeline to execute in parallel with the divide. The DS block has a dedicated write port to the register file, and no special care is required when executing operations in parallel with divide or square root instructions. This is described more in *Parallel execution* on page 22-23.

## 19.8 VFP11 treatment of branch instructions

The VFP11 coprocessor does not directly provide branch instructions. Instead, the result of a floating-point compare instruction can be stored in the ARM11 condition code flags using the FMSTAT instruction. This enables the ARM11 branch instructions and conditional execution capabilities to be used for executing conditional floating-point code. See the *ARM Architecture Reference Manual* for information on the use of ARM11 conditional execution to test IEEE 754 standard predicates.

In some cases, full IEEE 754 standard comparisons are not required. Simple comparisons of single-precision data, such as comparisons to zero or to a constant, can be done using an FMRS transfer and the ARM11 CMP and CMN instructions. This method is faster in many cases than using an FCMP instruction followed by an FMSTAT instruction. For more information, see *Compliance with the IEEE 754 standard* on page 21-3 and *Comparisons* on page 21-6.

## 19.9 Writing optimal VFP11 code

The following guidelines provide significant performance increases for VFP11 code:

- Unless there is a read-after-write hazard, program most scalar operations to immediately follow each other. Instead of a VFP11 FMAC instruction, use either a single ARM11 instruction or a VFP11 load or store instruction after the following instructions:
  - a scalar double-precision multiply
  - a multiply and accumulate
  - a short vector instruction of length greater than one iteration.
- Avoid short vector divides and square roots. The VFP11 FMAC and DS pipelines are unavailable until the final iteration of the short vector DS operation issues from the Execute 1 stage. If the short vector DS operation can be separated, other VFP11 instructions can be issued in the cycles immediately following the divide or square root. See *Parallel execution* on page 22-23.
- The best performance for data-intensive applications requires double-buffering looped short vector instructions. The register banks can be divided to provide multiple independent working areas. To take advantage of the simultaneous execution of data transfer and short vector arithmetic instructions, follow the arithmetic instructions on one bank with load or store instructions on the other bank.
- Moves to and from control registers are serializing. Avoid placing these in loops or time-critical code.
- If fully compliant IEEE 754 standard comparisons are not required, avoid using FCMPE and FCMPEZ. Using an FMRS instruction with an ARM11 CMP or CMN can be faster for simple comparisons. See *Comparisons* on page 21-6.

## 19.10 VFP11 revision information

This manual describes the fifth version of the VFP11 coprocessor.

Updates in the fifth version of the VFP11 coprocessor are:

- corrections for errata
- update to the FPSID register to reflect the fifth version.

There are no other functional differences between the VFP11 fourth and fifth versions.

# Chapter 20

## VFP Register File

This chapter describes implementation-specific features of the VFP11 coprocessor that are useful to programmers. It contains the following sections:

- *About the register file* on page 20-2
- *Register file internal formats* on page 20-3
- *Decoding the register file* on page 20-5
- *Loading operands from ARM11 registers* on page 20-6
- *Maintaining consistency in register precision* on page 20-8
- *Data transfer between memory and VFP11 registers* on page 20-9
- *Access to register banks in CDP operations* on page 20-11.

## 20.1 About the register file

The register file is organized in four banks of eight registers. Each 32-bit register can store either a single-precision floating-point number or an integer.

Any consecutive pair of registers,  $[R_{\text{even}+1}]:[R_{\text{even}}]$ , can store a double-precision floating-point number. Because a load and store operation does not modify the data, the VFP11 registers can also be used as secondary data storage by another application that does not use floating-point values.

The register file can be configured as four circular buffers for use by short vector instructions in applications requiring high data throughput, such as filtering and graphics transforms. For short vector instructions, register addressing is circular within each bank. Because load and store operations do not circulate, you can load or store multiple banks, up to the entire register file, with a single instruction. Short vector operations obey certain rules specifying the conditions under which the registers in the argument list specify circular buffers or single-scalar registers. The LEN and STRIDE fields in the FPSCR register specify the number of operations performed by short vector instructions and the increment scheme within the circular register banks. More information and examples are in the *ARM Architecture Reference Manual*.

## 20.2 Register file internal formats

The VFPv2 architecture provides the option of an internal data format that is different from some or all of the external formats. In this implementation of the VFP11 coprocessor, data in the register file has the same format as data in memory. Load or store operations for single-precision, double-precision, or integer data do not modify the format as a consequence of the transfer. However, to ensure compatibility with future VFP implementations, use FLDMX/FSTMX instructions when saving context and restoring VFP11 registers. See the *ARM Architecture Reference Manual* for more information.

It is the responsibility of the programmer to be aware of the data type in each register. The hardware does not perform any checking of the agreement between the data type in the source registers and the data type expected by the instruction. Hardware always interprets the data according to the precision implied in the instruction.

Accessing a register that has not been initialized or loaded with valid data is Unpredictable. A way to detect access to an uninitialized register is to load all registers with *Signaling NaNs* (SNaNs) in the precision of the initial access of the register and enable the Invalid Operation exception.

### 20.2.1 Integer data format

The VFP11 coprocessor supports signed and unsigned 32-bit integers. Signed integers are treated as two's complement values. No modification to the data is implicit in a load, store, or transfer operation on integer data. The format of integer data within the register file is identical to the format in memory or in an ARM11 general-purpose register.

### 20.2.2 Single-precision data format

Figure 20-1 shows the single-precision bitfields.

**Figure 20-1 Single-precision data format**

The single-precision data format contains:

- the sign bit, bit [31]
- the exponent, bits [30:23]
- the fraction, bits [22:0].

The IEEE 754 standard defines the single-precision data format of the VFP11 coprocessor. Refer to the IEEE 754 standard for details about exponent bias, special formats, and numerical ranges.

### 20.2.3 Double-precision data format

Double-precision format has a *Most Significant Word* (MSW) and a *Least Significant Word* (LSW). Figure 20-2 shows the double-precision bitfields.

### Figure 20-2 Double-precision data format

The MSW contains:

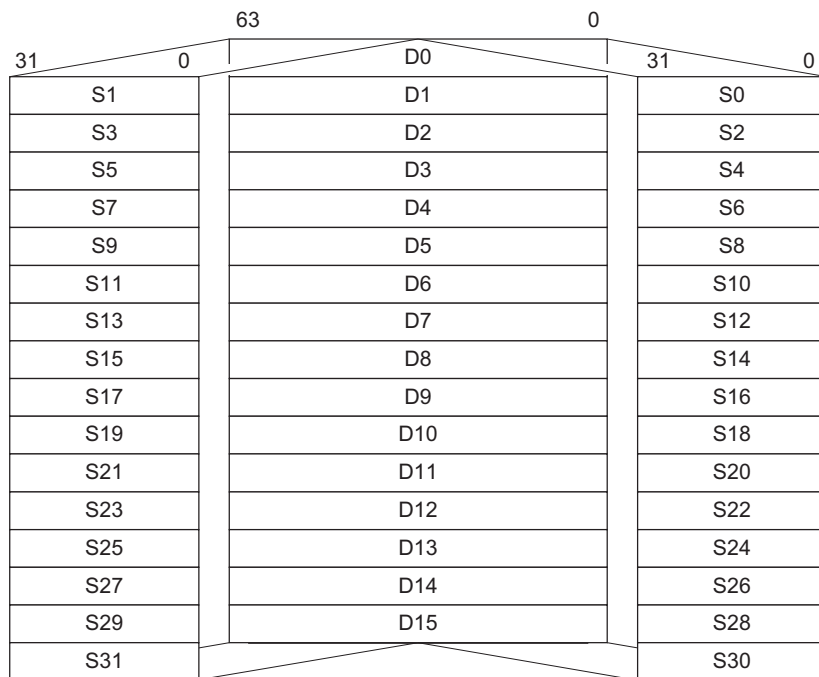

- the sign bit, bit [31]
- the exponent, bits [30:20]
- the upper 20 bits of the fraction, bits [19:0].

The LSW contains the lower 32 bits of the fraction.

The IEEE 754 standard defines the double-precision data format used in the VFP11 coprocessor. Refer to the IEEE 754 standard for details about exponent bias, special formats, and numerical ranges.

## 20.3 Decoding the register file

Each register file access uses the five bits of the register number in the instruction word. For single-precision and integer accesses, the most significant four bits are in the Fm, Fn, or Fd field, and the least significant bit is the M, N, or D bit for each instruction format. For instructions with double-precision operands or destinations, the M, N, and D bit corresponding to a double-precision access must be zero. Figure 20-3 shows the register file. See the *ARM Architecture Reference Manual* for instruction formats and the positions of these bits.

**Figure 20-3 Register file access**

## 20.4 Loading operands from ARM11 registers

Floating-point data can be transferred between ARM11 registers and VFP11 registers using the MCR, MRC, MCRR, and MRRC coprocessor data transfer instructions. No exceptions are possible on these transfer instructions.

MCR instructions transfer 32-bit values from ARM11 registers to VFP11 registers as Table 20-1 shows.

Table 20-1 VFP11 MCR instructions

| Instruction | Operation                  | Description                                                                                                 |
|-------------|----------------------------|-------------------------------------------------------------------------------------------------------------|
| FMXR        | VFP11 system register = Rd | Move from ARM11 register Rd to VFP11 system register FPSID <sup>a</sup> , FPSCR, FPEXC, FPINST, or FPINST2. |
| FMDLR       | Dn[31:0] = Rd              | Move from ARM11 register Rd to lower half of VFP11 double-precision register Dn.                            |
| FMDHR       | Dn[63:32] = Rd             | Move from ARM11 register Rd to upper half of VFP11 double-precision register Dn.                            |
| FMSR        | Sn = Rd                    | Move from ARM11 register Rd to VFP11 single-precision or integer register Sn.                               |

a. Writing to the FPSID register does not change the contents of the FPSID but may be used as a serializing instruction.

MRC instructions transfer 32-bit values from VFP11 registers to ARM11 registers as Table 20-2 shows.

Table 20-2 VFP11 MRC instructions

| Instruction | Operation                  | Description                                                                                   |
|-------------|----------------------------|-----------------------------------------------------------------------------------------------|
| FMRX        | Rd = VFP11 system register | Move from VFP11 system register FPSID, FPSCR, FPEXC, FPINST, or FPINST2 to ARM11 register Rd. |
| FMRDL       | Rd = Dn[31:0]              | Move from lower half of VFP11 double-precision register Dn to ARM11 register Rd.              |
| FMRDH       | Rd = Dn[63:32]             | Move from upper half of VFP11 double-precision register Dn to ARM11 register Rd.              |
| FMRS        | Rd = Sn                    | Move from VFP11 single-precision or integer register Sn to ARM11 register Rd.                 |

MCRR instructions transfer 64-bit quantities from ARM11 registers to VFP11 registers as Table 20-3 shows.

**Table 20-3 VFP11 MCRR instructions**

| Instruction | Operation                           | Description                                                                                                   |
|-------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------|
| FMDRR       | $Dm[31:0] = Rd$<br>$Dm[63:32] = Rn$ | Move from ARM11 registers $Rd$ and $Rn$ to lower and upper halves of VFP11 double-precision register $Dm$ .   |
| FMSRR       | $Sm = Rd$ $S(m + 1) = Rn$           | Move from ARM11 registers $Rd$ and $Rn$ to consecutive VFP11 single-precision registers $Sm$ and $S(m + 1)$ . |

MRRC instructions transfer 64-bit quantities from VFP11 registers to ARM11 registers as Table 20-4 shows.

**Table 20-4 VFP11 MRRC instructions**

| Instruction | Operation                           | Description                                                                                                 |
|-------------|-------------------------------------|-------------------------------------------------------------------------------------------------------------|
| FMRRD       | $Rd = Dm[31:0]$<br>$Rn = Dm[63:32]$ | Move from lower and upper halves of VFP11 double-precision register $Dm$ to ARM11 registers $Rd$ and $Rn$ . |
| FMRRS       | $Rd = Sm$ $Rn = S(m + 1)$           | Move from single-precision VFP11 registers $Sm$ and $S(m + 1)$ to ARM11 registers $Rd$ and $Rn$ .           |

## 20.5 Maintaining consistency in register precision

The VFP11 register file stores single-precision, double-precision, and integer data in the same registers. For example, D6 occupies the same registers as S12 and S13. The usable format of the register or registers depends on the last load or arithmetic instruction that wrote to the register or registers.

The VFP11 hardware does not check the register format to see if it is consistent with the precision of the current operation. Inconsistent use of the registers is possible but Unpredictable. The hardware interprets the data in the format required by the instruction regardless of the latest store or write operation to the register. It is the task of the compiler or programmer to maintain consistency in register usage.

## 20.6 Data transfer between memory and VFP11 registers

The B bit in the CP15 c1 Control Register (see Section B2 of the *ARM Architecture Reference Manual*), determines whether access to stored memory is little-endian or big-endian. The ARM11 processor supports both little-endian and big-endian access formats in memory.

The ARM11 processor stores 32-bit words in memory with the *Least Significant Byte* (LSB) in the lowest byte of the memory address regardless of the endianness selected. For a store of a single-precision floating-point value, the LSB is located at the target address with the lower two bits of the address cleared. The *Most Significant Byte* (MSB) is at the target address with the lower two bits set. For best performance, all single-precision data must be aligned in memory to four-byte boundaries, and double-precision data must be aligned to eight-byte boundaries.

Table 20-5 shows how single-precision data is stored in memory and the address to access each byte in both little-endian and big-endian formats. In this example, the target address is 0x40000000.

**Table 20-5 Single-precision data memory images and byte addresses**

| Single-precision data bytes | Address in memory | Little-endian byte address | Big-endian byte address |
|-----------------------------|-------------------|----------------------------|-------------------------|
| MSB, bits [31:24]           | 0x40000003        | 0x40000003                 | 0x40000000              |
| Bits [23:16]                | 0x40000002        | 0x40000002                 | 0x40000001              |
| Bits [15:8]                 | 0x40000001        | 0x40000001                 | 0x40000002              |
| LSB, bits [7:0]             | 0x40000000        | 0x40000000                 | 0x40000003              |

For double-precision data, the location of the two words that comprise the data are stored in different locations for little-endian and big-endian data access formats. Table 20-6 shows the data storage in memory and the address to access each byte in little-endian and big-endian access modes. In this example, the target address is 0x40000000.

**Table 20-6 Double-precision data memory images and byte addresses**

| <b>Double- precision data bytes</b> | <b>Little-endian address in memory</b> | <b>Little-endian byte address</b> | <b>Big-endian address in memory</b> | <b>Big-endian byte address</b> |
|-------------------------------------|----------------------------------------|-----------------------------------|-------------------------------------|--------------------------------|
| MSB, bits [63:56]                   | 0x40000007                             | 0x40000007                        | 0x40000003                          | 0x40000000                     |
| Bits [55:48]                        | 0x40000006                             | 0x40000006                        | 0x40000002                          | 0x40000001                     |
| Bits [47:40]                        | 0x40000005                             | 0x40000005                        | 0x40000001                          | 0x40000002                     |
| Bits [39:32]                        | 0x40000004                             | 0x40000004                        | 0x40000000                          | 0x40000003                     |
| Bits [31:24]                        | 0x40000003                             | 0x40000003                        | 0x40000007                          | 0x40000004                     |
| Bits [23:16]                        | 0x40000002                             | 0x40000002                        | 0x40000006                          | 0x40000005                     |
| Bits [15:8]                         | 0x40000001                             | 0x40000001                        | 0x40000005                          | 0x40000006                     |
| LSB, bits [7:0]                     | 0x40000000                             | 0x40000000                        | 0x40000004                          | 0x40000007                     |

The memory image for the data is identical for both little-endian and big-endian within data words. The ARM11 hardware performs the address transformations to provide both little-endian and big-endian addressing to the programmer.

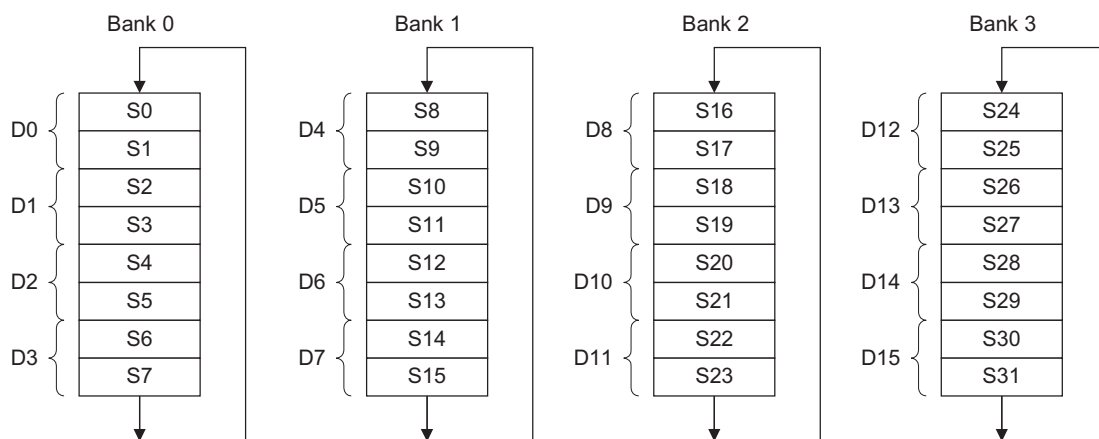

## 20.7 Access to register banks in CDP operations

The register file is especially suited for short vector operations. The four register banks function as four circular hardware queues. Short vector operations significantly improve the performance of operations with high data throughput such as signal processing and matrix manipulation functions.

### 20.7.1 About register banks

As Figure 20-4 shows, the register file is divided into four banks with eight registers in each bank for single-precision instructions and four registers per bank for double-precision instructions. CDP instructions access the banks in a circular manner. Load and store multiple instructions do not access the registers in a circular manner but treat the register file as a linearly ordered structure.

See *ARM Architecture Reference Manual* for more information on VFP addressing modes.

**Figure 20-4 Register banks**

A short vector CDP operation that has a source or destination vector crossing a bank boundary wraps around and accesses the first register in the bank.

Example 20-1 on page 20-12 shows the iterations of the following short vector add instruction:

```
FADDS S11, S22, S31
```

In this instruction, the LEN field contains b101, selecting a vector length of six iterations, and the STRIDE field contains b00, selecting a vector stride of one.

**Example 20-1 Register bank wrapping**

---

|                     |                                                      |
|---------------------|------------------------------------------------------|
| FADDs S11, S22, S31 | ; 1st iteration                                      |
| FADDs S12, S23, S24 | ; 2nd iteration. The 2nd source vector wraps around  |
|                     | ; and accesses the 1st register in the 4th bank      |
| FADDs S13, S16, S25 | ; 3rd iteration. The 1st source vector wraps around  |

|                     | ; 2nd bank                                           |

---

**20.7.2 Operations using register banks**

The register file organization supports four types of operations described in the following sections:

- *Scalar-only instructions*
- *Short vector-only instructions* on page 20-13
- *Short vector instructions with scalar source* on page 20-13
- *Scalar instructions in short vector mode* on page 20-14.

See *Floating-Point Status and Control Register, FPSCR* on page 21-19 for details of the LEN and STRIDE fields and the FPSCR register.

**Scalar-only instructions**

An instruction is a scalar-only operation if the operands are treated as scalars and the result is a scalar.

Clearing the LEN field in the FPSCR register selects a vector length of one iteration. For example, if the LEN field contains b000, then the following operation writes the sum of the single-precision values in S21 and S22 to S12:

```
FADDs S12, S21, S22
```

Some instructions can operate only on scalar data regardless of the value in the LEN field. These instructions are:

**Compare operations**

FCMPS/D, FCMPZS/D, FCMPEs/D, and FCMPEZs/D.

**Integer conversions**

FTOUIS/D, FTOUIZS/D, FTOSIS/D, FTOSIZS/D, FUITOS/D, and FSITOS/D.

**Precision conversions**

FCVTDS and FCVTSD.

**Short vector-only instructions**

Vector-only instructions require that the value in the LEN field is nonzero, and that the destination and Fm registers are not in bank 0.

Example 20-2 shows the iterations of the following short vector instruction:

FMACS S16, S0, S8

In the example, the LEN field contains b011, selecting a vector length of four iterations, and the STRIDE field contains b00, selecting a vector stride of one.

**Example 20-2 Short vector instruction**

---

|                    |                          |
|--------------------|--------------------------|
| FMACS S16, S0, S8  | ; 1st iteration          |
| FMACS S17, S1, S9  | ; 2nd iteration          |
| FMACS S18, S2, S10 | ; 3rd iteration          |
| FMACS S19, S3, S11 | ; 4th and last iteration |

---

**Short vector instructions with scalar source**

The VFPv2 architecture enables a vector to be operated on by a scalar operand. The destination must be a vector, that is, not in bank 0, and the Fm operand must be in bank 0.

Example 20-3 on page 20-14 shows the iterations of the following short vector instruction with a scalar source:

FMULD D12, D8, D2

In the example, the LEN field contains b001, selecting a vector length of two iterations, and the STRIDE field contains b00, selecting a vector stride of one.

**Example 20-3 Short vector instruction with scalar source**

---

```
FMULD D12, D8, D2 ; 1st iteration
FMULD D13, D9, D2 ; 2nd and last iteration
```

---

This scales the two source registers, D8 and D9, by the value in D2 and writes the new values to D12 and D13.

**Scalar instructions in short vector mode**

You can mix scalar and short vector operations by carefully selecting the source and destination registers. If the destination is in bank 0, the operation is scalar-only regardless of the value in the LEN field. You do not have to change the LEN field from a nonzero value to b000 to perform scalar operations.

Example 20-4 shows the sequence of operations for the following instructions:

```
FABSD D4, D8
FADDS S0, S0, S31
FMULS S24, S26, S1
```

In the example, the LEN field contains b001, selecting a vector length of two iterations, and the STRIDE field contains b00, selecting a vector stride of one.

**Example 20-4 Scalar operation in short vector mode**

---

```
FABSD D4, D8 ;vector DP ABS operation on regs (D8, D9) to (D4, D5)
FABSD D5, D9
FADDS S0, S0, S31 ; scalar increment of S0 by S31
FMULS S24, S26, S1 ; vector (S26, S27) scaled by S1 and written to (S24, S25)
FMULS S25, S27, S1
```

---

The tables that follow show the four types of operations possible in the VFPv2 architecture. In the tables, *Any* refers to the availability of all registers in the precision for the specified operand. *S* refers to a scalar operand with only a single register. *V* refers to a vector operand with multiple registers. Table 20-7 describes single-precision three-operand register usage.

**Table 20-7 Single-precision three-operand register usage**

| LEN field | Fd   | Fn  | Fm   | Operation type          |
|-----------|------|-----|------|-------------------------|
| b000      | Any  | Any | Any  | S = S op S OR S = S S S |
| Nonzero   | 0-7  | Any | Any  | S = S op S OR S = S S S |
| Nonzero   | 8-31 | Any | 0-7  | V = V op S OR V = V V S |
| Nonzero   | 8-31 | Any | 8-31 | V = V op V OR V = V V V |

Table 20-8 describes single-precision two-operand register usage.

**Table 20-8 Single-precision two-operand register usage**

| LEN field | Fd   | Fm   | Operation type |
|-----------|------|------|----------------|
| b000      | Any  | Any  | S = op S       |
| Nonzero   | 0-7  | Any  | S = op S       |
| Nonzero   | 8-31 | 0-7  | V = op S       |
| Nonzero   | 8-31 | 8-31 | V = op V       |

Table 20-9 describes double-precision three-operand register usage.

**Table 20-9 Double-precision three-operand register usage**

| LEN field | Fd   | Fn  | Fm   | Operation type          |
|-----------|------|-----|------|-------------------------|
| b000      | Any  | Any | Any  | S = S op S OR S = S S S |
| Nonzero   | 0-3  | Any | Any  | S = S op S OR S = S S S |
| Nonzero   | 4-15 | Any | 0-3  | V = V op S OR V = V V S |
| Nonzero   | 4-15 | Any | 4-15 | V = V op V OR V = V V V |

Table 20-10 describes double-precision two-operand register usage.

**Table 20-10 Double-precision two-operand register usage**

| LEN field | Fd   | Fm   | Operation type |
|-----------|------|------|----------------|
| b000      | Any  | Any  | S = op S       |
| Nonzero   | 0-3  | Any  | S = op S       |
| Nonzero   | 4-15 | 0-3  | V = op S       |
| Nonzero   | 4-15 | 4-15 | V = op V       |

# Chapter 21

## VFP Programmer's Model

This chapter describes implementation-specific features of the VFP11 coprocessor that are useful to programmers. It contains the following sections:

- *About the programmer's model* on page 21-2
- *Compliance with the IEEE 754 standard* on page 21-3
- *ARMv5TE coprocessor extensions* on page 21-10
- *VFP11 system registers* on page 21-16.

## 21.1 About the programmer's model

This section introduces the VFP11 implementation of the VFPv2 floating-point architecture.

---

### Note

---

The *ARM Architecture Reference Manual* describes the VFPv1 architecture.

---

The VFP11 coprocessor implements all the instructions and modes of the VFPv2 architecture. The VFPv2 architecture adds the following features and enhancements to the VFPv1 architecture:

- The ARM v5TE instruction set. This includes the MRRC and MCRR instructions to transfer 64-bit data between the ARM11 processor and the VFP11 coprocessor. These instructions enable the transfer of a double-precision register or two consecutively numbered single-precision registers to or from a pair of ARM11 registers. See *Loading operands from ARM11 registers* on page 20-6 for syntax and usage of VFP MRRC and MCRR instructions.
- Default NaN mode. In default NaN mode, any operation involving one or more NaN operands produces the default NaN as a result, rather than returning the NaN or one of the NaNs involved in the operation. This mode is compatible with the IEEE 754 standard but not with current handling of NaNs by industry.
- Addition of the input subnormal flag, IDC (FPSCR[7]). IDC is set whenever the VFP11 coprocessor is in flush-to-zero mode and a subnormal input operand is replaced by a positive zero. It remains set until cleared by writing to the FPSCR register. A new Input Subnormal exception enable bit, IDE (FPSCR[15]), is also added. When IDE is set, the VFP11 coprocessor traps to the Undefined trap handler for an instruction that has a subnormal input operand.
- New functionality of the underflow flag, UFC (FPSCR[3]), in flush-to-zero mode. In flush-to-zero mode, UFC is set whenever a result is below the threshold for normal numbers before rounding, and the result is flushed to zero. UFC remains set until cleared by writing to the FPSCR register. Setting the Underflow exception enable bit, UFE (FPSCR[11]), does not cause a trap in flush-to-zero mode.
- New functionality of the inexact flag, IXC (FPSCR[4]), in flush-to-zero mode. In VFPv1, IXC is set when an input or result is flushed to zero. In VFPv2 architecture, the IDC and UFC flags provide this information. See *Inexact exception* on page 23-23 for more information.
- Addition of RunFast mode. See *RunFast mode* on page 19-13 for details of RunFast mode operation.

## 21.2 Compliance with the IEEE 754 standard

This section introduces issues related to compliance with the IEEE 754 standard:

- hardware and software components
- software-based components and their availability.

See the *ARM Architecture Reference Manual* for more information about VFP architecture compliance with the IEEE 754 standard.

### 21.2.1 An IEEE 754 standard-compliant implementation

The VFP11 hardware and support code together provide VFPv2 floating-point instruction implementations that are compliant with the IEEE 754 standard. Unless an enabled floating-point exception occurs, it appears to the program that the floating-point instruction was executed by the hardware. If an exceptional condition occurs that requires software support during instruction execution, the instruction takes significantly more cycles than normal to produce the result. This is a common practice in the industry, and the incidence of such instructions is typically very low.

### 21.2.2 Complete implementation of the IEEE 754 standard

The following operations from the IEEE 754 standard are not supplied by the VFP11 instruction set:

- remainder
- round floating-point number to integer-valued floating-point number
- binary-to-decimal conversions
- decimal-to-binary conversions
- direct comparison of single-precision and double-precision values.

For complete implementation of the IEEE 754 standard, the VFP11 coprocessor and support code must be augmented with library functions that implement these operations. See *Application Note 98, VFP Support Code* for details of support code and the available library functions.

### 21.2.3 IEEE 754 standard implementation choices

Some of the implementation choices permitted by the IEEE 754 standard and used in the VFPv2 architecture are described in the *ARM Architecture Reference Manual*.

Additional implementation choices are made within the VFP11 coprocessor about which cases are handled by the VFP11 hardware and which cases bounce to the support code.

To execute frequently encountered operations as fast as possible and minimize silicon area, handling of rarely occurring values and some exceptions is relegated to the support code. The VFP11 coprocessor supports two modes for handling rarely occurring values:

### **Full-compliance mode**

Full-compliance mode with support code assistance is fully compliant with the IEEE 754 standard. Full-compliance mode requires the floating-point support code to handle certain operands and exceptional conditions not supported in the hardware. Although the support code gives full compliance with the IEEE 754 standard, it does increase the runtime of an application and the size of kernel code.

### **RunFast mode**

In RunFast mode, default handling of subnormal inputs, underflows, and NaN inputs is not fully compliant with the IEEE 754 standard. No user trap handlers are permitted in RunFast mode.

When flush-to-zero and default NaN modes are enabled, and all exceptions are disabled, the VFP11 coprocessor operates in RunFast mode. While the potential loss of accuracy for very small values is present, RunFast mode removes a significant number of performance-limiting stall conditions. By not requiring the floating-point support code, RunFast mode enables increased performance of typical and optimized code and a reduction in the size of kernel code. See *Hazards* on page 22-7 for more information on performance improvements in RunFast mode.

### **Supported formats**

The supported formats are:

- Single-precision and double-precision. No extended format is supported.
- Integer formats:
  - unsigned 32-bit integers
  - two's complement signed 32-bit integers.

NaN handling

Any single-precision or double-precision values with the maximum exponent field value and a nonzero fraction field are valid NaNs. A most significant fraction bit of zero indicates a *Signaling NaN* (SNaN). A one indicates a *Quiet NaN* (QNaN). Two NaN values are treated as different NaNs if they differ in any bit. Table 21-1 shows the default NaN values in both single and double precision.

Table 21-1 Default NaN values

|          | Single-precision                         | Double-precision                          |
|----------|------------------------------------------|-------------------------------------------|
| Sign     | 0                                        | 0                                         |
| Exponent | 0xFF                                     | 0x7FF                                     |
| Fraction | Bit [22] = 1<br>Bits [21:0] are all zero | Bit [51] = 1<br>Bits [50:0] are all zeros |

Any SNaN passed as input to an operation causes an Invalid Operation exception and sets the IOC flag, FPSCR[0]. If the IOE bit, FPSCR[8], is set, control passes to a user trap handler if present. If IOE is not set, a default QNaN is written to the destination register. The rules for cases involving multiple NaN operands are in the *ARM Architecture Reference Manual*.

Processing of input NaNs for ARM floating-point coprocessors and libraries is defined as follows:

- In full-compliance mode, NaNs are handled according to the *ARM Architecture Reference Manual*. The hardware does not process the NaNs directly for arithmetic CDP instructions, but traps to the support code for all NaN processing. For data transfer operations, NaNs are transferred without raising the Invalid Operation exception or trapping to support code. For the nonarithmetic CDP instructions, FABS, FNEG, and FCPY, NaNs are copied, with a change of sign if specified in the instructions, without causing the Invalid Operation exception or trapping to support code.
- In default NaN mode, NaNs are handled completely within the hardware without support code assistance. SNaNs in an arithmetic CDP operation set the IOC flag, FPSCR[0]. NaN handling by data transfer and nonarithmetic CDP instructions is the same as in full-compliance mode. Arithmetic CDP instructions involving NaN operands return the default NaN regardless of the fractions of any NaN operands.

Table 21-2 summarizes the effects of NaN operands on instruction execution.

Table 21-2 QNaN and SNaN handling

| Instruction type  | Default NaN mode | With QNaN operand                                                                                    | With SNaN operand                                                                                                                |
|-------------------|------------------|------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Arithmetic CDP    | Off              | INV <sup>a</sup> set. Bounce to support code to process operation.                                   | INV set. Bounce to support code to process operation.                                                                            |
|                   | On               | No bounce. Default NaN returns.                                                                      | IOC <sup>b</sup> set. If IOE <sup>c</sup> set, bounce to Invalid Operation user trap handler. If IOE clear, default NaN returns. |
| Nonarithmetic CDP | Off              | NaN passes to destination with sign changed as appropriate.                                          |                                                                                                                                  |
|                   | On               |                                                                                                      |                                                                                                                                  |
| FCMP(Z)           | Off              | INV set. Bounce to support code to process operation.                                                | INV set. Bounce to support code to process operation.                                                                            |
|                   | On               | No bounce. Unordered compare.                                                                        | IOC set. If IOE set, bounce to Invalid Operation user trap handler. If IOE clear, unordered compare.                             |
| FCMPE(Z)          | Off              | INV set. Bounce to support code to process operation.                                                | INV set. Bounce to support code to process operation.                                                                            |
|                   | On               | IOC set. If IOE set, bounce to Invalid Operation user trap handler. If IOE clear, unordered compare. | IOC set. If IOE set, bounce to Invalid Operation user trap handler. If IOE clear, unordered compare.                             |
| Load/store        | Off              | All NaNs transferred. No bounce.                                                                     |                                                                                                                                  |
|                   | On               |                                                                                                      |                                                                                                                                  |

- a. INV is the Input exception flag, FPEXC[7].
- b. IOC is the Invalid Operation exception flag, FPSCR[0].
- c. IOE is the Invalid Operation exception enable bit, FPSCR[8].

Comparisons

Comparison results modify condition code flags in the FPSCR register. The FMSTAT instruction transfers the current condition code flags in the FPSCR register to the ARM11 CPSR register. See the *ARM Architecture Reference Manual* for mapping of IEEE 754 standard predicates to ARM conditions. The condition code flags used are chosen so that subsequent conditional execution of ARM instructions can test the predicates defined in the IEEE 754 standard.

The VFP11 coprocessor handles most comparisons of numeric values in hardware, generating the appropriate condition code depending on whether the result is less than, equal to, or greater than. When the VFP11 coprocessor is not in flush-to-zero mode, comparisons involving subnormal operands bounce to support code.

The VFP11 coprocessor supports:

### Compare operations

The compare operations are FCMPS, FCMPZS, FCMPSD, and FCMPSD.

In default NaN mode, a compare instruction involving a QNaN produces an unordered result. An SNaN produces an unordered result and generates an Invalid Operation exception. If the IOE bit, FPSCR[8], is set, the Invalid Operation user trap handler is called. When the VFP11 coprocessor is not in default NaN mode, comparisons involving NaNs bounce to support code.

### Compare with exception operations

The compare with exception operations are FCMPEX, FCMPEXZ, FCMPEXD, and FCMPEXD.

In default NaN mode, a compare with exception operation involving either an SNaN or a QNaN produces an unordered result and generates an Invalid Operation exception. When the VFP11 coprocessor is not in default NaN mode, comparisons involving NaNs bounce to support code.

Some simple comparisons on single-precision data can be computed directly by the ARM11 processor. If only equality or comparison to zero is required, and NaNs are not an issue, performing the comparison in ARM11 registers using CMP or CMN instructions can be faster.

If branching on the state of the Z flag is required, you can use the following instructions for positive values:

```
FMRS Rx, Sn
CMP Rx, #0
BEQ label
```

If the input values can include negative numbers, including negative zero, you can use the following code:

```
FMRS Rx, Sn
CMP Rx, #0x80000000
CMPNE Rx, #0
BEQ label
```

Using a temporary register is even faster:

```
FMRS Rx, Sn
MOVS Rt, Rx, LSL #1
BEQ label
```

Comparisons with particular values are also possible. For example, to check if a positive value is greater or equal to +1.0, use:

```
FMRS Rx, Sn
CMP Rx, #0x3F800000
BGE label
```

When comparisons are required for double-precision values, or when IEEE 754 standard comparisons are required, it is safer to use the FCMP and FCMPE instructions with FMSTAT.

## Underflow

In the generation of Underflow exceptions, the *after rounding* form of *tininess* and the *subnormalization loss* form of *loss of accuracy* as described in the IEEE 754 standard are used.

In flush-to-zero mode, results that are tiny before rounding, as described in the IEEE 754 standard, are flushed to a positive zero, and the UFC flag, FPSCR[3], is set. Support code is not involved. See the *ARM Architecture Reference Manual* for information on flush-to-zero mode.

When the VFP11 coprocessor is not in flush-to-zero mode, any operation with a risk of producing a tiny result bounces to support code. If the operation does not produce a tiny result, it returns the computed result, and the UFC flag, FPSCR[3], is not set. The IXC flag, FPSCR[4], is set if the operation is inexact. If the operation produces a tiny result, the result is a subnormal or zero value, and the UFC flag, FPSCR[3], is set. See *Underflow exception* on page 23-21 for more information on underflow handling.

## Exceptions

Exceptions are taken in the VFP11 coprocessor in an imprecise manner. When exception processing begins, the states of the ARM11 processor and the VFP11 coprocessor might not be the same as when the exception occurred. Exceptional instructions cause the VFP11 coprocessor to enter the exceptional state, and the next VFP11 instruction triggers exception processing. After the issue of the exceptional instruction and before exception processing begins, non-VFP11 instructions and some VFP11 instructions can be executed and retired. Any source registers involved in the exceptional instruction are preserved, and the destination register is not overwritten on entry to the support code. If the detected exception enable bit is not set, the support code returns to the program flow at the point of the trigger instruction after processing the exception. If the detected exception enable bit is set, and a user trap handler is installed,

the support code passes control to the user trap handler. If the exception is overflow or underflow, the intermediate result specified by the IEEE 754 standard is made available to the user trap handler.

21.3 ARMv5TE coprocessor extensions

This section describes the syntax and usage of the four ARMv5TE architecture coprocessor extension instructions:

- *FMDRR*
- *FMRRD* on page 21-11
- *FMSRR* on page 21-12
- *FMRRS* on page 21-13.

———— **Note** ————

These instructions are implementations of the MCRR and MRRC instructions. See the the *ARM Architecture Reference Manual* for more information.

21.3.1 FMDRR

FMDRR transfers data from two ARM11 registers to a VFP11 double-precision register. The ARM11 registers do not have to be contiguous. Figure 21-1 shows the format of the FMDRR instruction.

Figure 21-1 FMDRR instruction format

**Syntax**

FMDRR {<cond>} <Dm>, <Rd>, <Rn>

where:

- <cond> Is the condition under which the instruction is executed. If <cond> is omitted, the AL (always) condition is used.
- <Dm> Specifies the destination double-precision VFP11 coprocessor register.
- <Rd> Specifies the source ARM11 register for the lower 32 bits of the operand.
- <Rn> Specifies the source ARM11 register for the upper 32 bits of the operand.

**Architecture version**

D variants only

Exceptions

None

Operation

```
if ConditionPassed(cond) then
 Dm[upper half] = Rn
 Dm[lower half] = Rd
```

Notes

**Conversions** In the programmer's model, FMDRR does not perform any conversion of the value transferred. Arithmetic instructions using either Rd or Rn treat the value as an integer, whereas most VFP instructions treat the Dm value as a double-precision floating-point number.

21.3.2 FMRRD

FMRRD transfers data in a VFP11 double-precision register to two ARM11 registers. The ARM11 registers do not have to be contiguous. Figure 21-2 shows the format of the FMRRD instruction.

Figure 21-2 FMRRD instruction format

Syntax

```
FMRRD {<cond>} <Rd>, <Rn>, <Dm>
```

where:

- <cond> Is the condition under which the instruction is executed. If <cond> is omitted, the AL (always) condition is used.
- <Rd> Specifies the destination ARM11 register for the lower 32 bits of the operand.
- <Rn> Specifies the destination ARM11 register for the upper 32 bits of the operand.
- <Dm> Specifies the source double-precision VFP11 coprocessor register.

Architecture version

D variants only

Exceptions

None

Operation

```
if ConditionPassed(cond) then
 Rn = Dm[upper half]
 Rd = Dm[lower half]
```

Notes

**Use of r15** If r15 is specified for <Rd> or <Rn>, the results are Unpredictable.

**Conversions** In the programmer's model, FMRRD does not perform any conversion of the value transferred. Arithmetic instructions using Rd and Rn treat the contents as an integer, whereas most VFP instructions treat the Dm value as a double-precision floating-point number.

21.3.3 FMSRR

FMSRR transfers data in two ARM11 registers to two consecutively numbered single-precision VFP11 registers, Sm and S(m + 1). The ARM11 registers do not have to be contiguous. Figure 21-3 shows the format of the FMSRR instruction.

Figure 21-3 FMSRR instruction format

Syntax

```
FMSRR {<cond>} <registers>, <Rd>, <Rn>
```

where:

<cond> Is the condition under which the instruction is executed. If <cond> is omitted, the AL (always) condition is used.

- <registers> Specifies the pair of consecutively numbered single-precision destination VFP11 registers, separated by a comma and surrounded by brackets. If  $m$  is the number of the first register in the list, the list is encoded in the instruction by setting  $S_m$  to the top four bits of  $m$  and  $M$  to the bottom bit of  $m$ . For example, if <registers> is {S1, S2}, the  $S_m$  field of the instruction is b0000 and the  $M$  bit is 1.
- <Rd> Specifies the source ARM11 register for the  $S_m$  VFP11 single-precision register.
- <Rn> Specifies the source ARM11 register for the  $S(m + 1)$  VFP11 single-precision register.

### Architecture version

All

### Exceptions

None

### Operation

If ConditionPassed(cond) then  
 $S_m = R_d$   
 $S(m + 1) = R_n$

### Notes

**Conversions** In the programmer's model, FMSRR does not perform any conversion of the value transferred. Arithmetic instructions using  $R_d$  and  $R_n$  treat the contents as an integer, whereas most VFP instructions treat the  $S_m$  and  $S(m + 1)$  values as single-precision floating-point numbers.

### Invalid register lists

If  $S_m$  is b1111 and  $M$  is 1 (an encoding of S31) the instruction is Unpredictable.

## 21.3.4 FMRRS

FMRRS transfers data in two consecutively numbered single-precision VFP11 registers to two ARM11 registers. The ARM11 registers do not have to be contiguous. Figure 21-4 on page 21-14 shows the format of the FMRRS instruction.

Figure 21-4 FMRRS instruction format

## Syntax

FMRRS {<cond>} <Rd>, <Rn>, <registers>

where:

- <cond> Is the condition under which the instruction is executed. If <cond> is omitted, the AL (always) condition is used.
- <Rd> Specifies the destination ARM11 register for the Sm VFP11 coprocessor single-precision value.
- <Rn> Specifies the destination ARM11 register for the S(m + 1) VFP11 coprocessor single-precision value.
- <registers> Specifies the pair of consecutively numbered single-precision VFP11 source registers, separated by a comma and surrounded by brackets. If m is the number of the first register in the list, the list is encoded in the instruction by setting Sm to the top four bits of m and M to the bottom bit of m. For example, if <registers> is {S16, S17}, the Sm field of the instruction is b1000 and the M bit is 0.

## Architecture version

All

## Exceptions

None

## Operation

If ConditionPassed(cond) then  
     Rd = Sm  
     Rn = S(m + 1)

**Notes**

**Conversions** In the programmer's model, FMRRS does not perform any conversion of the value transferred. Arithmetic instructions using Rd and Rn treat the contents as an integer, whereas most VFP11 instructions treat the Sm and S(m + 1) values as single-precision floating-point numbers.

**Invalid register lists**

If Sm is b1111 and M is 1 (an encoding of S31) the instruction is Unpredictable.

**Use of r15** If r15 is specified for Rd or Rn, the results are Unpredictable.

## 21.4 VFP11 system registers

The VFPv2 architecture describes the following three system registers that must be present in a VFP system:

- *Floating-Point System ID Register, FPSID*
- *Floating-Point Status and Control Register, FPSCR*
- *Floating-Point Exception Register, FPEXC.*

The VFP11 coprocessor provides sufficient information for processing all exceptional conditions encountered by the hardware. In an exceptional situation, the hardware provides:

- the exceptional instruction
- the instruction that might have been issued to the VFP11 coprocessor before detection of the exception
- exception status information:
  - type of exception
  - number of remaining short vector iterations after an exceptional iteration.

To support exceptional conditions, the VFP11 coprocessor provides two additional registers:

- *Floating-Point Instruction Register, FPINST*
- *Floating-Point Instruction Register 2, FPINST2.*

Also, the FPEXC register contains additional bits to support exceptional conditions.

These registers are designed to be used with the support code software available from ARM Limited. As a result, this document does not fully specify exception handling in all cases.

The coprocessor also provides two feature registers:

- *Media and VFP Feature Register 0* on page 21-25, MVFR0
- *Media and VFP Feature Register 1* on page 21-26, MVFR1.

Table 21-3 lists the VFP11 system registers.

**Table 21-3 VFP11 system registers**

| Register                                          | Access mode | Access type | Reset state |
|---------------------------------------------------|-------------|-------------|-------------|
| Floating-Point System ID Register, FPSID          | Any         | Read-only   | 0x41012085  |
| Floating-Point Status and Control Register, FPSCR | Any         | Read/write  | 0x00000000  |
| Floating-Point Exception Register, FPEXC          | Privileged  | Read/write  | 0x00000000  |

**Table 21-3 VFP11 system registers (continued)**

| <b>Register</b>                                | <b>Access mode</b> | <b>Access type</b> | <b>Reset state</b> |
|------------------------------------------------|--------------------|--------------------|--------------------|
| Floating-Point Instruction Register, FPINST    | Privileged         | Read/write         | 0xEE000A00         |
| Floating-Point Instruction Register 2, FPINST2 | Privileged         | Read/write         | UNP                |
| Media and VFP Feature Register 0, MVFR0        | Any                | Read-only          | 0x11111111         |
| Media and VFP Feature Register 1, MVFR1        | Any                | Read-only          | 0x00000000         |

Use the FMRX instruction to transfer the contents of VFP11 registers to ARM11 registers and the FMXR instruction to transfer the contents of ARM11 registers to VFP11 registers.

Table 21-4 lists the ARM11 processor modes for accessing the VFP11 system registers.

**Table 21-4 Accessing VFP11 system registers**

| <b>ARM11 processor mode</b> |                                    |                                  |                                   |
|-----------------------------|------------------------------------|----------------------------------|-----------------------------------|
| <b>Register</b>             | <b>FMXR/FMRX &lt;reg&gt; field</b> | <b>VFP11 coprocessor enabled</b> | <b>VFP11 coprocessor disabled</b> |
| FPSID                       | b0000                              | Any mode                         | Privileged mode                   |
| FPSCR                       | b0001                              | Any mode                         | None <sup>a</sup>                 |
| FPEXC                       | b1000                              | Privileged mode                  | Privileged mode                   |
| FPINST                      | b1001                              | Privileged mode                  | Privileged mode                   |
| FPINST2                     | b1010                              | Privileged mode                  | Privileged mode                   |
| MVFR0                       | b0111                              | Any mode                         | Privileged mode                   |
| MVFR1                       | b0110                              | Any mode                         | Privileged mode                   |

a. An instruction that tries to access FPSCR while the VFP11 coprocessor is disabled takes the Undefined Instruction trap.

Table 21-4 shows that a privileged ARM11 mode is sometimes required to access a VFP11 system register. When a privileged mode is required, an instruction that tries to access a register in a Non-privileged mode takes the Undefined Instruction trap.

The following sections describe the VFP11 system registers:

- *Floating-Point System ID Register, FPSID* on page 21-18
- *Floating-Point Status and Control Register, FPSCR* on page 21-19

- *Floating-point exception register, FPEXC* on page 21-22
- *Instruction registers, FPINST and FPINST2* on page 21-24.

21.4.1 Floating-Point System ID Register, FPSID

FPSID is a read-only register that identifies the VFP11 coprocessor. Figure 21-5 shows the FPSID bitfields.

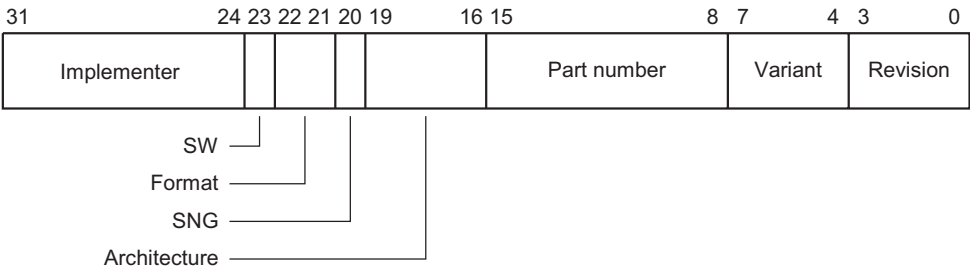

Figure 21-5 Floating-Point System ID Register

Table 21-5 describes the FPSID bitfields.

Table 21-5 FPSID bitfields

| Bit     | Meaning              | Value                                                          |

21.4.2 Floating-Point Status and Control Register, FPSCR

FPSCR is a read/write register that can be accessed in both privileged and unprivileged modes. All bits described as SBZ in Figure 21-6 are reserved for future expansion. They must be initialized to zeros. To ensure that these bits are not modified, code other than initialization code must use read/modify/write techniques when writing to FPSCR. Failure to observe this rule can cause Unpredictable results in future systems. Figure 21-6 shows the FPSCR bitfields.

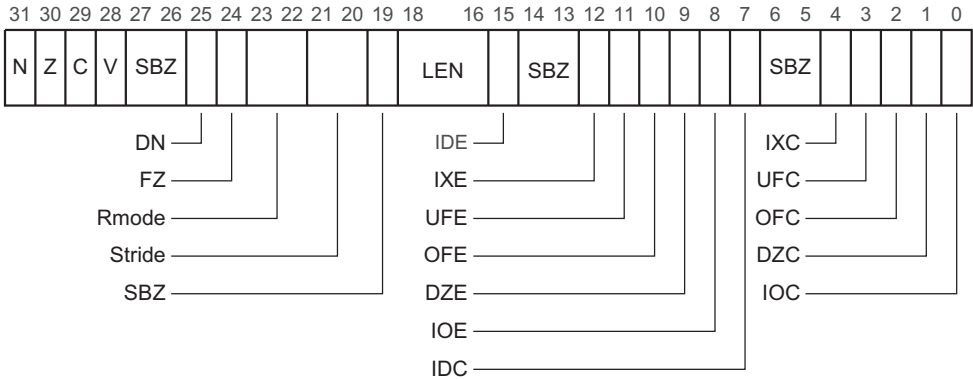

Figure 21-6 Floating-Point Status and Control Register

Table 21-6 describes the FPSCR bitfields.

**Table 21-6 Encoding of the Floating-Point Status and Control Register**

| Bit     | Name   | Meaning                                                                                                                                                                                               |
|---------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [31]    | N      | Set if comparison produces a <i>less than</i> result                                                                                                                                                  |
| [30]    | Z      | Set if comparison produces an <i>equal</i> result                                                                                                                                                     |
| [29]    | C      | Set if comparison produces an <i>equal</i> , <i>greater than</i> , or <i>unordered</i> result                                                                                                         |
| [28]    | V      | Set if comparison produces an <i>unordered</i> result                                                                                                                                                 |
| [27:26] | -      | Should Be Zero                                                                                                                                                                                        |
| [25]    | DN     | Default NaN mode enable bit:<br>1 = default NaN mode enabled<br>0 = default NaN mode disabled                                                                                                         |

| [0]   | IOC  | Invalid Operation cumulative flag |

### Vector length and stride control

FPSCR[18:16] is the LEN field and controls the vector length for VFP instructions that operate on short vectors. The vector length is the number of iterations in a short vector instruction.

FPSCR[21:20] is the STRIDE field and controls the vector stride. The vector stride is the increment value used to select the registers involved in the next iteration of the short vector instruction.

The rules for vector operation do not permit a vector to use the same register more than once. LEN and STRIDE combinations that use a register more than once produce Unpredictable results, as Table 21-7 shows. Some combinations that work normally in single-precision short vector instructions cause Unpredictable results in double-precision instructions.

**Table 21-7 Vector length and stride combinations**

| LEN  | Vector length | STRIDE | Vector stride | Single-precision vector instructions | Double-precision vector instructions |
|------|---------------|--------|---------------|--------------------------------------|--------------------------------------|
| b000 | 1             | b00    | -             | All instructions are scalar          | All instructions are scalar          |
| b000 | 1             | b11    | -             | Unpredictable                        | Unpredictable                        |
| b001 | 2             | b00    | 1             | Work normally                        | Work normally                        |
| b001 | 2             | b11    | 2             | Work normally                        | Work normally                        |
| b010 | 3             | b00    | 1             | Work normally                        | Work normally                        |

**Table 21-7 Vector length and stride combinations (continued)**

| <b>LEN</b> | <b>Vector length</b> | <b>STRIDE</b> | <b>Vector stride</b> | <b>Single-precision vector instructions</b> | <b>Double-precision vector instructions</b> |

| b110       | 7                    | b00           | 1                    | Work normally                               | Unpredictable                               |
| b110       | 7                    | b11           | 2                    | Unpredictable                               | Unpredictable                               |
| b111       | 8                    | b00           | 1                    | Work normally                               | Unpredictable                               |
| b111       | 8                    | b11           | 2                    | Unpredictable                               | Unpredictable                               |

### 21.4.3 Floating-point exception register, FPExc

In a bounce situation, the FPExc register records the exceptional status. The FPExc register information assists the support code in processing the exceptional condition or reporting the condition to a system trap handler or a user trap handler.

You must save and restore the FPExc register whenever changing the context. If the EX flag, FPExc[31], is set, then the VFP11 coprocessor is in the exceptional state, and you must also save and restore the FPINST and FPINST2 registers. You can write the context switch code to determine from the EX flag which registers to save and restore or to simply save all three.

The EN bit, FPExc[30], is the VFP enable bit. Clearing EN disables the VFP11 coprocessor. The VFP11 coprocessor clears the EN bit on reset.

The INV flag, FPExc[7], signals Input exceptions. An Input exception is a condition in which the hardware cannot process one or more input operands according to the architectural specifications. This includes subnormal inputs when the VFP11 coprocessor is not in flush-to-zero mode and NaNs when the VFP11 coprocessor is not in default NaN mode.

The UFC flag, FPEXC[3], is set whenever an operation has the potential to generate a result that is below the minimum threshold for the destination precision.

The OFC flag, FPEXC[2], is set whenever an operation has the potential to generate a result that, after rounding, exceeds the largest representable number in the destination format.

The IOC flag, FPEXC[0], is set whenever an operation has the potential to generate a result that cannot be represented or is not defined.

**Note**

To prevent an infinite loop of exceptions, the support code must clear the EX flag, FPEXC[31], immediately on entry to the exception code. All exception flags must be cleared before returning from exception code to user code.

Figure 21-7 shows the FPEXC bitfields.

**Figure 21-7 Floating-Point Exception Register**

Table 21-8 describes the bitfields of the FPEXC register.

**Table 21-8 Encoding of the Floating-Point Exception Register**

| Bit  | Name | Description                                                                                                                                    |
|------|------|------------------------------------------------------------------------------------------------------------------------------------------------|
| [31] | EX   | Exception flag.<br>When EX is set, the VFP11 coprocessor is in the exceptional state.<br>EX must be cleared by the exception handling routine. |
| [30] | EN   | VFP enable bit.<br>Setting EN enables the VFP11 coprocessor. Reset clears EN.                                                                  |
| [29] | -    | Should Be Zero.                                                                                                                                |

**Table 21-8 Encoding of the Floating-Point Exception Register (continued)**

| Bit     | Name   | Description                                                                                                                                                                                                                                                                                                                                                 |
|---------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [28]    | FP2V   | FPINST2 instruction valid flag. Set when FPINST2 contains a valid instruction. FP2V must be cleared by the exception handling routine.                                                                                                                                                                                                                      |
| [27:11] | -      | Should Be Zero.                                                                                                                                                                                                                                                                                                                                             |
| [10:8]  | VECITR | Vector iteration count field.<br>VECITR contains the number of remaining short vector iterations after a potential exception was detected in one of the iterations:<br>b000 = 1 iteration<br>b001 = 2 iterations<br>b010 = 3 iterations<br>b011 = 4 iterations<br>b100 = 5 iterations<br>b101 = 6 iterations<br>b110 = 7 iterations<br>b111 = 0 iterations. |
| [7]     | INV    | Input exception flag.<br>Set if the VFP11 coprocessor is not in flush-to-zero mode and an operand is subnormal or if the VFP11 coprocessor is not in default NaN mode and an operand is a NaN.                                                                                                                                                              |
| [6:4]   | -      | Should Be Zero.                                                                                                                                                                                                                                                                                                                                             |
| [3]     | UFC    | Potential underflow flag.<br>Set if the VFP11 coprocessor is not in flush-to-zero mode and a potential underflow condition exists.                                                                                                                                                                                                                          |
| [2]     | OFC    | Potential overflow flag.<br>Set if the OFE bit, FPSCR[10], is set, the VFP11 coprocessor is not in RunFast mode, and a potential overflow condition exists.                                                                                                                                                                                                 |
| [1]     | -      | Should Be Zero.                                                                                                                                                                                                                                                                                                                                             |
| [0]     | IOC    | Potential invalid operation flag.<br>Set if the IOE bit, FPSCR[8], is set, the VFP11 coprocessor is not in RunFast mode, and a potential invalid operation condition exists.                                                                                                                                                                                |

#### 21.4.4 Instruction registers, FPINST and FPINST2

The VFP11 coprocessor has two instruction registers:

- The FPINST register contains the exceptional instruction.

- The FPINST2 register contains the instruction that was issued to the VFP11 coprocessor before the exception was detected. This instruction was retired in the ARM11 processor and cannot be reissued. It must be executed by support code.

The FPINST and FPINST2 are accessible only in privileged modes.

The instruction in the FPINST register is in the same format as the issued instruction but is modified in several ways. The condition code flags, FPINST[31:28], are forced to b1110, the AL (always) condition. If the instruction is a short vector, the source and destination registers that reference vectors are updated to point to the source and destination registers of the exceptional iteration. See *Exception processing for CDP short vector instructions* on page 23-9 for more information.

The instruction in the FPINST2 register is in the same format as the issued instruction but is modified by forcing the condition code flags, FPINST2[31:28] to b1110, the AL (always) condition.

## 21.4.5 Media and VFP Feature Register 0

The purpose of the Media and VFP Feature Register 0 is to provide information about the features that the VFP unit contains.

Media and VFP Feature Register 0 is:

- a 32-bit read-only register
- accessible in any mode when the VFP is enabled by the EN bit, see *Floating-point exception register; FPEXC* on page 21-22
- accessible only in Privileged modes when the VFP is disabled by the EN bit.

Figure 21-8 shows the bit arrangement for Media and VFP Feature Register 0.

|    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |
|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|
| 31 | 28 | 27 | 24 | 23 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 4 | 3 | 0 |
| -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | - | - | - | - | - |

**Figure 21-8 Media and VFP Feature Register 0 format**

Table 21-9 shows how the bit values correspond with the Media and VFP Feature Register 0 functions.

**Table 21-9 Media and VFP Feature Register 0 bit functions**

| Bits    | Field | Function                                                                                                                                                                                                                                                                                       |

The values in the Media and VFP Feature Register 0 are implementation defined.

#### 21.4.6 Media and VFP Feature Register 1

The purpose of the Media and VFP Feature Register 1 is to provide information about the features that the VFP unit contains.

Media and VFP Feature Register 1 is:

- a 32-bit read-only register
- accessible in any mode when the VFP is enabled by the EN bit, see *Floating-point exception register, FPEXC* on page 21-22

- accessible only in Privileged modes when the VFP is disabled by the EN bit.

Figure 21-9 shows the bit arrangement for Media and VFP Feature Register 1.

Figure 21-9 Media and VFP Feature Register 1 format

Table 21-10 shows how the bit values correspond with the Media and VFP Feature Register 1 functions.

Table 21-10 Media and VFP Feature Register 1 bit functions

| Bits    | Field | Function                                                                                                                            |

# Chapter 22

## VFP Instruction Execution

This chapter describes the VFP11 instruction pipeline and its relationship with the ARM processor instruction pipeline. It contains the following sections:

- *About instruction execution* on page 22-2
- *Serializing instructions* on page 22-3
- *Interrupting the VFP11 coprocessor* on page 22-4
- *Forwarding* on page 22-5
- *Hazards* on page 22-7
- *Operation of the scoreboards* on page 22-8
- *Data hazards in full-compliance mode* on page 22-15
- *Data hazards in RunFast mode* on page 22-19
- *Resource hazards* on page 22-20
- *Parallel execution* on page 22-23
- *Execution timing* on page 22-25.

## 22.1 About instruction execution

Features of the VFP11 implementation of the instruction pipelines include the following:

- The FMXR, FMRX, and FMSTAT instructions stall in the VFP11 LS pipeline until all currently executing instructions are completed. You can use these *serializing* instructions to:
  - capture condition codes and exception status
  - modify the mode of operation of subsequent instructions
  - create an exception boundary.
 See *Serializing instructions* on page 22-3.
- Load or store instructions that cause a Data Abort exception restart after interrupt service. LDM and STM instructions detect exceptional conditions after the first transfer and restart after interrupt service if reissued.
 

See *Interrupting the VFP11 coprocessor* on page 22-4.
- To reduce stall time, the VFP11 coprocessor forwards data:
  - from load instructions to CDP instructions
  - from CDP instructions to CDP instructions.
 See *Forwarding* on page 22-5.
- In full-compliance mode, the VFP11 coprocessor implements full data hazard and resource hazard detection.
 

RunFast mode guarantees no instruction bouncing for applications that require less strict hazard detection.

See *Hazards* on page 22-7 and *Operation of the scoreboards* on page 22-8.
- The L/S, FMAC, and DS pipelines operate independently, enabling data transfer and CDP operations to execute in parallel.
 

See *Parallel execution* on page 22-23.

*Execution timing* on page 22-25 describes VFP11 instruction throughput and latency.

## 22.2 Serializing instructions

A serializing instruction is one that stalls because of activity in the VFP11 pipelines without the presence of a register or resource hazard. In general, an access to a VFP11 control or status register is a serializing instruction.

The serializing instructions are FMRX and FMXR, including the FMSTAT instruction. Serializing instructions stall the VFP11 coprocessor in the Issue stage and the ARM processor in the Execute 2 stage until:

- the VFP11 pipeline is past the point of updating either the condition codes or the exception status
- a write to a system register can no longer affect the operation of a current or pending instruction.

An FMRX or FMSTAT instruction stalls until all prior floating-point operations are completed, and the data to be written by the VFP11 coprocessor is valid. For example, a compare operation updates the FPSCR register condition codes in the Writeback stage of the compare.

An FMXR instruction stalls until all prior floating-point operations are past the point of being affected by the instruction. For example, writing to the FPSCR register stalls until the point when changing the control bits cannot affect any operation currently executing or awaiting execution. Writing to the FPEXC, FPINST, or FPINST2 register stalls until the pipeline is completely clear.

Uses of serializing instructions include:

- capturing condition codes and exception status
- delineating a block of instructions for execution with the ability to capture the exception status of that block of instructions
- modifying the mode of operation of subsequent instructions, such as the rounding mode or vector length.

While no instruction can change the contents of the FPSID register, you can access the FPSID register with FMRX or FMXR as a general-purpose serializing operation or to create an exception boundary.

## 22.3 Interrupting the VFP11 coprocessor

Instructions are issued to the VFP11 coprocessor directly from the ARM prefetch unit. The VFP11 coprocessor has no external interface beyond the ARM processor and cannot be separately interrupted by external sources. Any interrupt that causes a change of flow in the ARM11 processor is also reflected to the VFP11 coprocessor. Any VFP instruction that is cancelled because of condition code failure in the ARM11 pipeline is also cancelled in the VFP11 pipeline.

If the interrupt is the result of a Data Abort condition, the load or store operation that caused the abort restarts after interrupt processing is complete. Load and store multiple instructions can detect some exception conditions and interrupt the operation after the initial transfer. If the load or store instruction is reissued after interrupt processing, it can restart with the initial transfer. The source data is guaranteed to be unchanged, and no operations that depend on the load or store data can execute until the load or store operation is complete.

When interrupt processing begins, there can be a delay before the VFP11 coprocessor is available to the interrupt routine. Any prior short vector instruction that passes the ARM11 Execute 2 stage also passes the VFP11 Execute 1 stage and executes to completion uninterrupted. The maximum delay during which the VFP11 coprocessor is unavailable is equal to the time it takes to process a short vector of eight single-precision divide or square root iterations. Such an operation can cause a delay of as many as 114 cycles after the short vector divide or square root enters the VFP11 Execute 1 stage.

In systems that require fast response time and access to the VFP11 coprocessor by the service routine, avoid short vector divide and short vector square root operations. All other instructions, including short vector instructions, have little or no impact. Limiting the number of VFP11 registers that must be saved and used in the service routine also reduces startup time. If the VFP11 coprocessor is not required in the service routine, you can disable it with EN bit (FPEXC[30]). This eliminates the necessity of saving the VFP11 coprocessor state. See *Application Note 98, VFP Support Code*.

## 22.4 Forwarding

In general, any forwarding operation reduces the stall time of a dependent instruction by one cycle. The VFP11 coprocessor forwards data from load instructions to CDP instructions and from CDP instructions to CDP instructions.

The VFP11 coprocessor does not forward in the following cases:

- from an instruction that produces integer data
- to a store instruction (FST, FSTM, MRC, or MRRC)
- to an instruction of different precision.

In the examples that follow, the stall counts given are based on two data transfer assumptions:

- accesses by load operations result in cache hits and are able to deliver one or two data words per cycle
- store operations write directly to the write buffer or cache and can transfer one or two data words per cycle.

When these assumptions are valid, the VFP11 coprocessor operates at its highest performance. When these assumptions are not valid, load and store operations are affected by the delay required to access data. Example 22-1 to Example 22-3 on page 22-6 illustrate the capabilities of the VFP11 coprocessor in ideal conditions.

In Example 22-1, the second FADDS instruction depends on the result of the first FADDS instruction. The result of the first FADDS instruction is forwarded, reducing the stall from eight cycles to seven cycles.

### Example 22-1 Data forwarded to dependent instruction

---

```
FADDS S1, S2, S3
FADDS S8, S9, S1
```

---

In Example 22-2, there is no data forwarding of the double-precision FMULD data in D2 to the single-precision FADDS data in S5, even though S5 is the upper half of D2.

### Example 22-2 Mixed-precision data not forwarded

---

```
FMULD D2, D0, D1
FADDS S12, S13, S5
```

---

In Example 22-3, the double-precision FSTD stalls for eight cycles until the result of the FMULD is written to the register file. No forwarding is done from the FMULD to the store instruction.

**Example 22-3 Data not forwarded to store instruction**

---

```
FMULD D1, D2, D3
FSTD D1, [Rx]
```

---

## 22.5 Hazards

The VFP11 coprocessor incorporates full hazard detection with a fully-interlocked pipeline protocol. No compiler scheduling is required to avoid hazard conditions. The source and destination scoreboards process interlocks caused by unavailable source or destination registers or by unavailable data. The scoreboards stall instructions until all data operands and destination registers are available before the instruction is issued to the instruction pipeline.

The determination of hazards and interlock conditions is different in full-compliance mode and RunFast mode. RunFast mode guarantees no bounce conditions and has a less strict hazard detection mechanism, enabling instructions to begin execution earlier than in full-compliance mode.

There are two VFP11 pipeline hazards:

- A data hazard is a combination of instructions that creates the potential for operands to be accessed in the wrong order.
  - A *Read-After-Write* (RAW) data hazard occurs when the pipeline creates the potential for an instruction to read an operand before a prior instruction writes to it. It is a hazard to the intended read-after-write operand access.
  - A *Write-After-Read* (WAR) data hazard occurs when the pipeline creates the potential for an instruction to write to a register before a prior instruction reads it. It is a hazard to the intended write-after-read operand access.
  - A *Write-After-Write* (WAW) data hazard occurs when the pipeline creates the potential for an instruction to write to a register before a prior instruction writes to it. It is a hazard to the intended write-after-write operand access.
- Resource hazard. See *Resource hazards* on page 22-20.

## 22.6 Operation of the scoreboards

The VFP11 processor detects all hazard conditions that exist between issued and executing instructions. It uses two scoreboards to ensure that all source and destination registers for an instruction contain valid data and are available for reading or writing:

- The destination scoreboard contains a lock for each destination register for the current operation.
- The source scoreboard contains a lock for each source register for the current operation.

In the Decode stage of the VFP11 pipeline, the VFP11 coprocessor determines which source and destination registers are involved in an operation and generates a lock mask for them. In a short vector operation, the lock mask includes the registers involved in every iteration of the operation. In the Issue stage, the VFP11 coprocessor checks and updates the source and destination scoreboards. If it detects a hazard between the instruction in the Issue stage and a prior instruction, the scoreboards are not updated, and the instruction stalls in the Issue stage.

A VFP11 instruction can begin execution only when its source and destination registers are free of locks. A short vector operation can begin only when the registers for all its iterations are free of locks. When a short vector instruction proceeds in the pipeline beyond the Issue stage, all the registers involved in the operation are locked.

The source scoreboard clears a source register lock in the first Execute 1 stage of the pipeline or in the first Execute 1 stage of the iteration. In store multiple instructions, the source scoreboard clears source register locks in the Execute stage in which the instruction writes the store data to the ARM11 processor.

The destination scoreboard clears the destination register lock in the cycle before the result data is written back to the register file or is available for forwarding (Execute 7 in the FMAC pipeline, Execute 4 in the DS pipeline). In a load operation, the destination scoreboard normally clears the destination register lock in the Memory 2 stage. If the load is delayed, the destination scoreboard clears the destination register lock in the same cycle as the writeback to the register file.

### 22.6.1 Scoreboard operation when an instruction bounces

When a bounce occurs in full-compliance mode, support code is called to complete the operation and to deliver the result and the exception status to the user trap handler. The source scoreboard ensures that all source registers for the operation are preserved for the support code. In a short vector operation, this includes the source registers for the

bounced iteration and for any iterations remaining after the bounced iteration. The preserved source registers include the destination register for a multiply and accumulate instruction.

Because RunFast mode guarantees that no bouncing is possible, source registers do not have to be preserved after they are used by the instruction. For all scalar operations and nonmultiple store operations, no source registers are locked in RunFast mode. In short vector operations, the length of the vector determines which source registers are locked. When the vector length exceeds four single-precision iterations, the source scoreboard locks the source registers for iterations 5 and above. When the vector length exceeds two double-precision iterations, the source scoreboard locks the source registers for iterations 3 and above.

## 22.6.2 Single-precision source register locking

In full-compliance mode, the source scoreboard locks all source registers in the Issue stage of the instruction. In RunFast mode, the source scoreboard locks the source registers for only iterations 5, 6, 7, and 8. Table 22-1 summarizes source register locking in single-precision operations.

**Table 22-1 Single-precision source register locking**

| Source registers locked in Issue stage |               |                         |                         |
|----------------------------------------|---------------|-------------------------|-------------------------|
| LEN                                    | Vector length | Full-compliance mode    | RunFast mode            |
| b000                                   | 1             | Iteration 1 registers   | -                       |
| b001                                   | 2             | Iteration 1-2 registers | -                       |
| b010                                   | 3             | Iteration 1-3 registers | -                       |
| b011                                   | 4             | Iteration 1-4 registers | -                       |
| b100                                   | 5             | Iteration 1-5 registers | Iteration 5 registers   |
| b101                                   | 6             | Iteration 1-6 registers | Iteration 5-6 registers |
| b110                                   | 7             | Iteration 1-7 registers | Iteration 5-7 registers |
| b111                                   | 8             | Iteration 1-8 registers | Iteration 5-8 registers |

For the following single-precision short vector instruction, the LEN field contains b100, selecting a vector length of five iterations:

FADD S8, S16, S24

The FADD instruction performs the following operations:

```
FADD S8, S16, S24
FADD S9, S17, S25
FADD S10, S18, S26
FADD S11, S19, S27
FADD S12, S20, S28
```

In full-compliance mode, the source scoreboard locks S16-S20 and S24-S28 in the Issue stage of the instruction.

In RunFast mode, the source scoreboard locks only the fifth iteration source registers, S20 and S28.

22.6.3 Single-precision source register clearing

In full-compliance mode, the source scoreboard clears the source registers of each iteration in the Execute 1 stage of the iteration. In RunFast mode, the source registers for only iterations 5, 6, 7, and 8 are locked, and the source scoreboard begins clearing them in the second Execute 1 cycle of the instruction. Table 22-2 summarizes source register clearing in single-precision operations.

Table 22-2 Single-precision source register clearing

| Source registers cleared in Execute 1 stage of each iteration |                       |                       |
|---------------------------------------------------------------|-----------------------|-----------------------|
| Execute 1 cycle                                               | Full-compliance mode  | RunFast mode          |
| 1                                                             | Iteration 1 registers | -                     |
| 2                                                             | Iteration 2 registers | Iteration 5 registers |
| 3                                                             | Iteration 3 registers | Iteration 6 registers |
| 4                                                             | Iteration 4 registers | Iteration 7 registers |
| 5                                                             | Iteration 5 registers | Iteration 8 registers |
| 6                                                             | Iteration 6 registers | -                     |
| 7                                                             | Iteration 7 registers | -                     |
| 8                                                             | Iteration 8 registers | -                     |

For the following single-precision short vector instruction, the LEN field contains b100, selecting a vector length of five iterations:

```
FADD S8, S16, S24
```

The FADD instruction performs the following operations:

```

FADDS S8, S16, S24
FADDS S9, S17, S25
FADDS S10, S18, S26
FADDS S11, S19, S27
FADDS S12, S20, S28

```

In full-compliance mode, the source scoreboard clears the source registers of each iteration in the Execute 1 cycle of the iteration.

In RunFast mode, the source scoreboard locks only the fifth iteration source registers, S20 and S28. It clears S20 and S28 in the second Execute 1 cycle of the instruction.

#### 22.6.4 Double-precision source register locking

In full-compliance mode, the source scoreboard locks all source registers in the Issue stage of the instruction. In RunFast mode, the source scoreboard locks the source registers for only iterations 3 and 4. Table 22-3 summarizes source register locking in double-precision operations.

**Table 22-3 Double-precision source register locking**

| LEN  | Vector length | Source registers locked in Issue stage |                         |
|------|---------------|----------------------------------------|-------------------------|
|      |               | Full-compliance mode                   | RunFast mode            |
| b000 | 1             | Iteration 1 registers                  | -                       |
| b001 | 2             | Iteration 1-2 registers                | -                       |
| b010 | 3             | Iteration 1-3 registers                | Iteration 3 registers   |
| b011 | 4             | Iteration 1-4 registers                | Iteration 3-4 registers |

For the following double-precision, short vector instruction, the LEN field contains b011, selecting a vector length of four iterations:

```
FADDD D4, D8, D12
```

The FADDD instruction performs the following operations:

```

FADDD D4, D8, D12
FADDD D5, D9, D13
FADDD D6, D10, D14
FADDD D7, D11, D15

```

In full-compliance mode, the source scoreboard locks D8-D11 and D12-D15 in the Issue stage of the instruction.

In RunFast mode, the source scoreboard locks only the third iteration source registers, D10 and D14, and the fourth iteration source registers, D11 and D15.

22.6.5 Double-precision source register clearing

The number of Execute 1 cycles required to clear the source registers of a double-precision instruction depends on the throughput of the instruction, as the following sections show:

- *Instructions with one-cycle throughput*
- *Instructions with two-cycle throughput* on page 22-13.

Instructions with one-cycle throughput

In full-compliance mode, the source scoreboard clears the source registers of each iteration in the Execute 1 stage of the iteration. In RunFast mode, the source registers for only iterations 3 and 4 are locked, and the source scoreboard begins clearing them in the first Execute 1 cycle of the instruction. Table 22-4 summarizes source register clearing for double-precision one-cycle instructions such as FADDD and FABSD.

Table 22-4 Double-precision source register clearing for one-cycle instructions

| Execute 1 cycle | Source registers cleared in Execute 1 stage of each iteration |                       |
|-----------------|---------------------------------------------------------------|-----------------------|
|                 | Full-compliance mode                                          | RunFast mode          |
| 1               | Iteration 1 registers                                         | Iteration 3 registers |
| 2               | Iteration 2 registers                                         | Iteration 4 registers |
| 3               | Iteration 3 registers                                         | -                     |
| 4               | Iteration 4 registers                                         | -                     |

For the following one-cycle, double-precision short vector instruction, the LEN field contains b011, selecting a vector length of four iterations:

FADDD D4, D8, D12

The FADDD performs the following operations:

FADDD D4, D8, D12  
FADDD D5, D9, D13  
FADDD D6, D10, D14  
FADDD D7, D11, D15

In full-compliance mode, the source scoreboard clears the source registers of each iteration in the Execute 1 cycle of the iteration.

In RunFast mode, the source scoreboard locks only the third iteration source registers, D10 and D14, and the fourth iteration source registers, D11 and D15. It clears D10 and D14 in the first Execute 1 cycle of the instruction and clears D11 and D15 in the second Execute 1 cycle.

### Instructions with two-cycle throughput

In full-compliance mode, the source scoreboard clears the source registers of each iteration in the first Execute 1 cycle of the iteration. In RunFast mode, the source registers for only iterations 3 and 4 are locked, and the source scoreboard begins clearing them in the first Execute 1 cycle of the instruction. Table 22-5 summarizes source register clearing for double-precision two-cycle instructions such as FMULD and FMACD.

**Table 22-5 Double-precision source register clearing for two-cycle instructions**

| Execute 1 cycle | Source registers cleared in Execute 1 stage of each iteration |                       |
|-----------------|---------------------------------------------------------------|-----------------------|
|                 | Full-compliance mode                                          | RunFast mode          |
| 1               | Iteration 1 registers                                         | Iteration 3 registers |
| 2               | -                                                             | -                     |
| 3               | Iteration 2 registers                                         | Iteration 4 registers |
| 4               | -                                                             | -                     |
| 5               | Iteration 3 registers                                         | -                     |
| 6               | -                                                             | -                     |
| 7               | Iteration 4 registers                                         | -                     |
| 8               | -                                                             | -                     |

For the following two-cycle, double-precision, short vector instruction, the LEN field contains b011, selecting a vector length of four iterations:

FMULD D4, D8, D12

The FMULD instruction performs the following operations:

FMULD D4, D8, D12

FMULD D5, D9, D13

FMULD D6, D10, D14  
FMULD D7, D11, D15

In full-compliance mode, the source scoreboard clears the source registers of each iteration in the first Execute 1 cycle of the iteration.

In RunFast mode, only the third iteration source registers, D10 and D14, and the fourth iteration source registers, D11 and D15, are locked. The source scoreboard clears D10 and D14 in the first Execute 1 cycle and clears D11 and D15 in the third Execute 1 cycle of the instruction.

## 22.7 Data hazards in full-compliance mode

The sections that follow give examples of data hazards in full-compliance mode:

- *Status register RAW hazard example*
- *Load multiple-CDP RAW hazard example*
- *CDP-CDP RAW hazard example* on page 22-17
- *Load multiple-short vector CDP RAW hazard example* on page 22-16
- *Short vector CDP-load multiple WAR hazard example* on page 22-17.

### 22.7.1 Status register RAW hazard example

In Example 22-4, the FMSTAT is stalled for four cycles in the Decode stage until the FCMPs updates the condition codes in the FPSCR register. Two cycles later, the FMSTAT writes the condition codes to the ARM11 processor.

**Example 22-4 FCMPs-FMSTAT RAW hazard**

---

FCMPs S1, S2  
FMSTAT

---

Table 22-6 shows the VFP11 pipeline stages for Example 22-4.

**Table 22-6 FCMPs-FMSTAT RAW hazard**

| Instruction cycle number |   |   |    |    |    |    |   |   |    |    |    |
|--------------------------|---|---|----|----|----|----|---|---|----|----|----|
| Instruction              | 1 | 2 | 3  | 4  | 5  | 6  | 7 | 8 | 9  | 10 | 11 |
| FCMPs                    | D | I | E1 | E2 | E3 | E4 | - | - | -  | -  | -  |
| FMSTAT                   | - | D | D  | D  | D  | D  | I | E | M1 | M2 | W  |

### 22.7.2 Load multiple-CDP RAW hazard example

In Example 22-5 on page 22-16, the FADDS is stalled in the Issue stage for six cycles until the FLDM makes its last transfer to the VFP11 coprocessor. S15 is forwarded from the load in cycle 9 to the FADDS.

Example 22-5 FLDM-FADDS RAW hazard

|                     |
|---------------------|
| FLDM [Rx], {S8-S15} |
| FADDS S1, S2, S15   |

Table 22-7 shows the VFP11 pipeline stages for Example 22-5.

Table 22-7 FLDM-FADDS RAW hazard

| Instruction cycle number |   |   |   |    |    |   |   |   |   |    |    |    |    |    |    |    |
|--------------------------|---|---|---|----|----|---|---|---|---|----|----|----|----|----|----|----|
| Instruction              | 1 | 2 | 3 | 4  | 5  | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
| FLDM                     | D | I | E | M1 | M2 | W | W | W | W | -  | -  | -  | -  | -  | -  | -  |
| FADDS                    | - | D | I | I  | I  | I | I | I | I | E1 | E2 | E3 | E4 | E5 | E6 | E7 |

22.7.3 Load multiple-short vector CDP RAW hazard example

In Example 22-6, the short vector FADDS is stalled in the Issue stage until the FLDM loads all source registers required by the FADDS. In this case, the FADDS is stalled for three cycles. Because the FADDS depends on the FLDM for only one register, S7, it does not have to wait for completion of the FLDM. The S7 data is forwarded in cycle 6. The LEN field contains b011, selecting a vector length of four iterations. The STRIDE field contains b00, selecting a vector stride of one. The first source vector uses registers S7, S0, S1, and S2, and the only FADDS source register loaded by the FLDM is S7. This example is based on the assumption that the remaining source and destination registers are available to the FADDS in cycle 6.

Example 22-6 FLDM-short vector FADDS RAW hazard

|                     |
|---------------------|
| FLDM [R2], {S7-S14} |
| FADDS S16, S7, S25  |

Table 22-8 shows the VFP11 pipeline stages of the FLDM and the first iteration of the short vector FADDS for Example 22-6 on page 22-16.

**Table 22-8 FLDM-short vector FADDS RAW hazard**

| Instruction cycle number |   |   |   |    |    |   |    |    |    |    |    |    |    |    |    |    |    |
|--------------------------|---|---|---|----|----|---|----|----|----|----|----|----|----|----|----|----|----|
| Instruction              | 1 | 2 | 3 | 4  | 5  | 6 | 7  | 8  | 9  | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 |
| FLDM                     | D | I | E | M1 | M2 | W | W  | W  | W  | -  | -  | -  | -  | -  | -  | -  | -  |
| FADDS                    | - | D | I | I  | I  | I | E1 | E1 | E1 | E1 | E2 | E3 | E4 | E5 | E6 | E7 | W  |

#### 22.7.4 CDP-CDP RAW hazard example

In Example 22-7, the FADDS is stalled in the Issue stage for seven cycles until the FMULS data is written and forwarded in cycle 10 to the Issue stage of the FADDS.

**Example 22-7 FMULS-FADDS RAW hazard**

---

FMULS S4, S1, S0  
FADDS S5, S4, S3

---

Table 22-9 shows the VFP11 pipeline stages of Example 22-7.

**Table 22-9 FMULS-FADDS RAW hazard**

| Instruction cycle number |   |   |    |    |    |    |    |    |    |    |    |
|--------------------------|---|---|----|----|----|----|----|----|----|----|----|
| Instruction              | 1 | 2 | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 |
| FMULS                    | D | I | E1 | E2 | E3 | E4 | E5 | E6 | E7 | W  | -  |
| FADDS                    | - | D | I  | I  | I  | I  | I  | I  | I  | I  | E1 |

#### 22.7.5 Short vector CDP-load multiple WAR hazard example

In Example 22-8 on page 22-18, the load multiple FLDMS creates a WAR hazard to the source registers of the FMULS. The LEN field contains b011, selecting a vector length of four iterations, and the STRIDE field contains b00, selecting a vector stride of one. The VFP11 coprocessor stalls the FLDMS until the FMULS clears the scoreboard locks for all the source registers, S16-S19 and S24-S27.

Example 22-8 Short vector FMULS-FLDMS WAR hazard

---

```
FMULS S8, S16, S24
FLDMS [R2], {S16-S27}
```

---

Table 22-10 shows the VFP11 pipeline stages for the first iteration of Example 22-8.

Table 22-10 Short vector FMULS-FLDMS WAR hazard

| Instruction cycle number |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------------------|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Instruction              | 1 | 2 | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
| FMULS                    | D | I | E1 | E1 | E1 | E1 | E2 | E3 | E4 | E5 | E6 | E7 | W  | -  | -  | -  |
| FLDMS                    | - | D | I  | I  | I  | I  | I  | E  | M1 | M2 | W  | W  | W  | W  | W  | W  |

## 22.8 Data hazards in RunFast mode

In RunFast mode, source registers for the FMAC and FMUL family of instructions are locked:

- when the vector length exceeds four iterations in single-precision instructions
- when the vector length exceeds two iterations in double-precision instructions.

No source registers are locked for scalar instructions.

### 22.8.1 Short vector CDP-load multiple WAR hazard example

Example 22-9 is the same as Example 22-8 on page 22-18. The LEN field contains b011, selecting a vector length of four iterations, and the STRIDE field contains b00, selecting a vector stride of one. Executing these instructions in RunFast mode reduces the cycle count of the FLDMS by four cycles.

#### Example 22-9 Short vector FMULS-FLDMS WAR hazard in RunFast mode

---

```
FMULS S8, S16, S24
FLDMS R2, {S16-S27}
```

---

Table 22-11 shows that the VFP11 coprocessor does not stall the FLDMS operation.

**Table 22-11 Short vector FMULS-FLDMS WAR hazard in RunFast mode**

| Instruction cycle number |   |   |    |    |    |    |    |    |    |    |    |    |    |
|--------------------------|---|---|----|----|----|----|----|----|----|----|----|----|----|
| Instruction              | 1 | 2 | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 | 13 |
| FMULS                    | D | I | E1 | E1 | E1 | E1 | E2 | E3 | E4 | E5 | E6 | E7 | W  |
| FLDMS                    | - | D | I  | E  | M1 | M2 | W  | W  | W  | W  | W  | W  | -  |

---

## 22.9 Resource hazards

A resource hazard exists when the pipeline required for an instruction is unavailable because of a prior instruction. VFP11 resource stalls are possible in the following cases:

- A data transfer operation following an incomplete data transfer operation can cause a resource stall. The ARM11 processor can stall each data transfer because of unavailable data caused by memory latency or a cache miss, increasing the latency of the data transfer instruction and stalling any following data transfer instructions.
- An arithmetic operation following either a short vector arithmetic operation or a double-precision multiply or multiply and accumulate operation can cause a resource stall. The latency for a double-precision multiply or multiply and accumulate operation is two cycles, causing a single-cycle stall for an arithmetic operation that immediately follows.
- A single-precision divide or square root operation stalls subsequent DS operations for 15 cycles. A double-precision divide or square root operation stalls subsequent DS operations for 29 cycles.
- A short vector divide or square root operation requires the FMAC pipeline for the first cycle of each iteration and stalls any following CDP operation. The following CDP operation stalls until the final iteration of the short vector divide or square root operation completes the Execute 1 stage.

The LS pipeline is separate from the FMAC and DS pipelines. No resource hazards exist between data transfer instructions and arithmetic instructions.

The sections that follow give examples of resource hazards:

- *Load multiple-load-CDP resource hazard example*
- *Load multiple-short vector CDP resource hazard example on page 22-21*
- *Short vector CDP-CDP resource hazard example on page 22-22.*

### 22.9.1 Load multiple-load-CDP resource hazard example

In Example 22-10 on page 22-21, the FLDM is executing two transfers to the VFP11 coprocessor. The FLDS is stalled behind the FLDM until the FLDM enters the final Execute cycle. The FADDS is stalled for one cycle until the FLDS begins execution.

**Example 22-10 FLDM-FLDS-FADDs resource hazard**

---

```

FLDM [R2], {S8-S10}
FLDS [R4], S16
FADDs S2, S3, S4

```

---

Table 22-12 shows the pipeline stages for Example 22-10.

**Table 22-12 FLDM-FLDS-FADDs resource hazard**

| Instruction cycle number |   |   |   |    |    |    |    |    |    |    |    |    |    |
|--------------------------|---|---|---|----|----|----|----|----|----|----|----|----|----|
| Instruction              | 1 | 2 | 3 | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 | 13 |
| FLDM                     | D | I | E | M1 | M2 | W  | W  | -  | -  | -  | -  | -  | -  |
| FLDS                     | - | D | D | I  | E  | M1 | M2 | W  | -  | -  | -  | -  | -  |
| FADDs                    | - | - | - | D  | I  | E1 | E2 | E3 | E4 | E5 | E6 | E7 | W  |

---

**22.9.2 Load multiple-short vector CDP resource hazard example**

In Example 22-11, no resource hazard exists for the FMULS because of the FLDM in the prior cycle. The FMULS is issued to the VFP11 coprocessor in the cycle following the issue of the FLDM, and executes in parallel with it.

The LEN field contains, b011, selecting a vector length of four iterations. The STRIDE field contains b00, selecting a vector stride of one.

**Example 22-11 FLDM-short vector FMULS resource hazard**

---

```

FLDM [R2], {S8-S10}
FMULS S16, S24, S4

```

---

Table 22-13 shows the pipeline stages for Example 22-11 on page 22-21.

Table 22-13 FLDM-short vector FMULS resource hazard

| Instruction cycle number |   |   |   |    |    |    |    |    |    |    |    |    |    |    |
|--------------------------|---|---|---|----|----|----|----|----|----|----|----|----|----|----|
| Instruction              | 1 | 2 | 3 | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 | 13 | 14 |
| FLDM                     | D | I | E | M1 | M2 | W  | W  | -  | -  | -  | -  | -  | -  | -  |
| FMULS                    | - | D | I | E1 | E1 | E1 | E1 | E2 | E3 | E4 | E5 | E6 | E7 | W  |

22.9.3 Short vector CDP-CDP resource hazard example

In Example 22-12, a short vector divide is followed by a FADDS instruction. The short vector divide has b001 in the LEN field, selecting a vector length of two iterations. It requires the Execute 1 stage of the FMAC pipeline for the first cycle of each iteration of the divide, resulting in a stall of the FADDS until the final iteration of the divide completes the first Execute 1 cycle. The divide iterates for 14 cycles in the Execute 1 and Execute 2 stages of the DS pipeline, shown in Table 22-14 as E1. The first and shared Execute 1 cycle for each divide iteration is designated as E1’.

Example 22-12 Short vector FDIVS-FADDS resource hazard

FDIVS S8, S10, S12  
FADDS S0, S0, S1

Table 22-14 shows the pipeline stages for Example 22-12.

Table 22-14 Short vector FDIVS-FADDS resource hazard

| Instruction cycle number |   |   |     |    |     |    |     |    |     |    |    |     |    |    |    |     |    |    |
|--------------------------|---|---|-----|----|-----|----|-----|----|-----|----|----|-----|----|----|----|-----|----|----|
| Instruction              | 1 | 2 | 3   | 4  | ... | 17 | 18  | 19 | ... | 25 | 26 | ... | 30 | 31 | 32 | ... | 35 | 36 |
| FDIVS                    | D | I | E1' | E1 | ... | E1 | E1' | E1 | ... | E1 | E1 | ... | E1 | E1 | E1 | ... | E4 | W  |
| FADDS                    | - | - | D   | D  | ... | D  | I   | E1 | ... | E7 | W  | ... | -  | -  | -  | ... | -  | -  |

## 22.10 Parallel execution

The VFP11 coprocessor is capable of execution in each of the three pipelines independently of the others and without blocking issue or writeback from any pipeline. Separate LS, FMAC, and DS pipelines allow for parallel operation of CDP and data transfer instructions. Scheduling instructions to take advantage of the parallelism that occurs when multiple instructions execute in the VFP11 pipelines can result in a significant improvement in program execution time.

A data transfer operation can begin execution if:

- no data hazards exist with any currently executing operations
- the LS pipeline is not currently stalled by the ARM11 processor or busy with a data transfer multiple.

A CDP can be issued to the FMAC pipeline if:

- no data hazards exist with any currently executing operations
- the FMAC pipeline is available (no short vector CDP is executing and no double-precision multiply is in the first cycle of the multiply operation)
- no short vector operation with unissued iterations is currently executing in either the FMAC or DS pipeline.

A divide or square root instruction can be issued to the DS pipeline if:

- no data hazards exist with any currently executing operations
- the DS pipeline is available (no current divide or square root is executing in the DS pipeline E1 stage)
- no short vector operation with unissued iterations is executing in the FMAC pipeline.

Example 22-13 on page 22-24 shows a case of the VFP11 coprocessor executing instructions in parallel in each of the three pipelines:

- a load multiple in the L/S pipeline
- a divide in the DS pipeline
- a short vector add in the FMAC pipeline.

In this example, the LEN field contains b011, selecting a vector length of four iterations, and the STRIDE field contains b00, for a vector stride of one.

Example 22-13 Parallel execution in all three pipelines

---

|                     |
|---------------------|
| FLDM [R4], {S4-S13} |
| FDIVSS0, S1, S2     |
| FADDS S16, S20, S24 |

---

Table 22-15 shows the pipeline progression of the three instructions.

Table 22-15 Parallel execution in all three pipelines

| Instruction cycle number |   |   |   |     |    |    |    |    |    |    |    |    |    |    |    |
|--------------------------|---|---|---|-----|----|----|----|----|----|----|----|----|----|----|----|
|                          | 1 | 2 | 3 | 4   | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 | 13 | 14 | 15 |
| FLDM                     | D | I | E | M1  | M2 | W  | W  | W  | W  | W  | -  | -  | -  | -  | -  |
| FDIVS                    | - | D | I | E1' | E1 | E1 | E1 | E1 | E1 | E1 | E1 | E1 | E1 | E1 | E1 |
| FADDS                    | - | - | D | I   | E1 | E1 | E1 | E1 | E2 | E3 | E4 | E5 | E6 | E7 | W  |

In Example 22-13, no data hazards exist between any of the three instructions. The load multiple is able to begin execution immediately, and data is transferred to the register file beginning in cycle 6. Because the destination is in bank 0, the FDIVS is a scalar operation and requires one cycle in the FMAC pipeline E1 stage. If the FDIVS were a short vector operation, the FADDS could not begin execution until the last FDIVS iteration passed the FMAC E1 pipeline stage. The FADDS is a short vector operation and requires the FMAC pipeline E1 stage for cycles 5-8.

————— **Note** —————

E1' is the first cycle in E1 and is in both FMAC and DS blocks. Subsequent E1 cycles represent the iteration cycles and occupy both E1 and E2 stages in the DS block.

—————

## 22.11 Execution timing

Complex instruction dependencies and memory system interactions make it impossible to describe briefly the exact cycle timing of all instructions in all circumstances. The timing described in Table 22-16 is accurate in most cases. For precise timing, you must use a cycle-accurate model of your ARM11 processor.

In Table 22-16, throughput is defined as the cycle after issue in which another instruction can begin execution. Instruction latency is the number of cycles after which the data is available for another operation. Forwarding reduces the latency by one cycle for operations that depend on floating-point data. Table 22-16 shows the throughput and latency for all VFP11 instructions.

**Table 22-16 Throughput and latency cycle counts for VFP11 instructions**

| Instructions                               | Single-precision |                    | Double-precision |                    |
|--------------------------------------------|------------------|--------------------|------------------|--------------------|
|                                            | Throughput       | Latency            | Throughput       | Latency            |
| FABS, FNEG, FCVT, FCPY                     | 1                | 4                  | 1                | 4                  |
| FCMP, FCMPE, FCMPZ, FCMPEZ                 | 1                | 4                  | 1                | 4                  |
| FSITO, FUITO, FTOSI, FTOUI, FTOUIZ, FTOSIZ | 1                | 8                  | 1                | 8                  |
| FADD, FSUB                                 | 1                | 8                  | 1                | 8                  |
| FMUL, FNMUL                                | 1                | 8                  | 2                | 9                  |
| FMAC, FNMAC, FMSC, FNMSC                   | 1                | 8                  | 2                | 9                  |
| FDIV, FSQRT                                | 15               | 19                 | 29               | 33                 |
| FLD <sup>a</sup>                           | 1                | 4                  | 1                | 4                  |
| FST <sup>a</sup>                           | 1 <sup>a</sup>   | System- dependent  | 1                | System- dependent  |
| FLDM <sup>a</sup>                          | X <sup>b</sup>   | X <sup>b</sup> + 3 | X <sup>b</sup>   | X <sup>b</sup> + 3 |
| FSTM <sup>a</sup>                          | X <sup>b</sup>   | System- dependent  | X <sup>b</sup>   | System- dependent  |
| FMSTAT                                     | 1                | 2                  | -                | -                  |
| FMSR/FMSRR <sup>c</sup>                    | 1                | 4                  | -                | -                  |
| FMDHR/FMDHC/FMDRR <sup>c</sup>             | -                | -                  | 1                | 4                  |
| FMRS/FMRRS <sup>c</sup>                    | 1                | 2                  | -                | -                  |

Table 22-16 Throughput and latency cycle counts for VFP11 instructions (continued)

| Instructions                   | Single-precision |         | Double-precision |         |
|--------------------------------|------------------|---------|------------------|---------|
|                                | Throughput       | Latency | Throughput       | Latency |
| FMRDH/FMRDL/FMRRD <sup>c</sup> | -                | -       | 1                | 2       |
| FMXR <sup>d</sup>              | 1                | 4       | -                | -       |
| FMRX <sup>d</sup>              | 1                | 2       | -                | -       |

- a. The cycle count for a load instruction is based on load data that is cached and available to the ARM11 processor from the cache. The cycle count for a store instruction is based on store data that is written to the cache and/or write buffer immediately. When the data is not cached or the write buffer is unavailable, the number of cycles also depends on the memory subsystem.
- b. The number of cycles represented by X is (N/2) if N is even or (N/2 + 1) if N is odd.
- c. FMDRR and FMRRD transfer one double-precision data per transfer. FMSRR and FMRRS transfer two single-precision data per transfer.
- d. FMXR and FMRX are serializing instructions. The latency depends on the register transferred and the current activity in the VFP11 coprocessor when the instruction is issued.

# Chapter 23

## VFP Exception Handling

This chapter describes VFP11 exception processing. It contains the following sections:

- *About exception processing* on page 23-2
- *Bounced instructions* on page 23-3
- *Support code* on page 23-5
- *Exception processing* on page 23-8
- *Input Subnormal exception* on page 23-14
- *Invalid Operation exception* on page 23-15
- *Division by Zero exception* on page 23-18
- *Overflow exception* on page 23-19
- *Underflow exception* on page 23-21
- *Inexact exception* on page 23-23
- *Input exceptions* on page 23-24
- *Arithmetic exceptions* on page 23-25.

## 23.1 About exception processing

The VFP11 coprocessor handles exceptions, other than inexact exceptions, imprecisely with respect to both the state of the ARM11 processor and the state of the VFP11 coprocessor. It detects an exceptional instruction after the instruction passes the point for exception handling in the ARM11 processor. It then enters the *exceptional state* and signals the presence of an exception by refusing to accept a subsequent VFP instruction. The instruction that triggers exception handling bounces to the ARM11 processor. The bounced instruction is not necessarily the instruction immediately following the exceptional instruction. Depending on sequence of instructions that follow, the bounce can occur several instructions later.

The VFP11 coprocessor can generate exceptions only on arithmetic operations. Data transfer operations between the ARM11 processor and the VFP11 coprocessor, and instructions that copy data between VFP11 registers, FCPY, FABS, and FNEG, cannot produce exceptions.

In full-compliance mode the VFP11 hardware and support code together process exceptions according to the IEEE 754 standard. VFP11 exception processing includes calling user trap handlers with intermediate operands specified by the IEEE 754 standard. In RunFast mode, the VFP11 coprocessor generates the default, or trap disabled, value when an overflow, invalid operation, division by zero, or inexact condition occurs. RunFast mode does not provide for user trap handlers.

For descriptions of each of the exception flags and their bounce characteristics, see *Input Subnormal exception* on page 23-14 to *Arithmetic exceptions* on page 23-25.

## 23.2 Bounced instructions

Normally, the VFP11 hardware executes floating-point instructions completely in hardware. However, the VFP11 coprocessor can, under certain circumstances, refuse to accept a floating-point instruction, causing the ARM Undefined Instruction exception. This is known as *bouncing* the instruction.

There are three reasons for bouncing an instruction:

- a prior instruction generates a potential or actual floating-point exception that cannot be properly handled by the VFP11 coprocessor, such as a potential underflow when the VFP11 coprocessor is not in flush-to-zero mode
- a prior instruction generates a potential or actual floating-point exception when the corresponding exception enable bit is set in the FPSCR, such as a square root of a negative value when the IOE bit, FPSCR[8], is set
- the current instruction is Undefined.

When a floating-point exception is detected, the VFP11 hardware sets the EX flag, FPEXC[31], and loads the FPINST register with a copy of the exceptional instruction. The VFP11 coprocessor is now in the *exceptional state*. The instruction that bounces as a result of the exceptional state is referred to as the *trigger* instruction.

See *Exception processing* on page 23-8.

### 23.2.1 Potential or actual exception that the VFP11 coprocessor cannot handle

Three exceptional conditions cannot be handled by the VFP11 hardware:

- an operation that might underflow when the VFP11 coprocessor is not in flush-to-zero mode
- an operation involving a subnormal operand when the VFP11 coprocessor is not in flush-to-zero mode
- an operation involving a NaN when the VFP11 coprocessor is not in default NaN mode.

For these conditions the VFP11 coprocessor relies on support code to process the operation. See *Underflow exception* on page 23-21 and *Input exceptions* on page 23-24.

### 23.2.2 Potential or actual exception with the exception enable bit set

The VFP11 coprocessor evaluates the instruction for exceptions in the E1 and E2 pipeline stages. No means exist to signal exceptions to the ARM11 processor after the E2 stage. The VFP11 coprocessor enters the exceptional state when it detects that an

instruction has a potential to generate a floating-point exception while the corresponding exception enable bit is set. Such an instruction is called a *potentially exceptional instruction*.

An example of an instruction that generates an actual exception is a division of a normal value by zero when the Division by Zero exception enable bit, FPSCR[9], is set. This mechanism provides support for the IEEE 754 trap mechanism and provides programmers a means of halting execution on certain conditions.

As an example of an instruction that generates a potential exception, if the overflow exception enable bit, FPSCR[10], is set, and the initial exponent for a multiply operation is the maximum exponent for a normal value in the destination precision, the VFP11 coprocessor bounces the instruction pessimistically. Because the impact on the exponent as a result of mantissa overflow and rounding is not known in the E1 or E2 stages of the FMAC pipeline, the decision to bounce must be made based on the potential for an exception. Support code performs the multiply operation and determines the exception status. If the multiply operation results in an overflow, the processor jumps to the Overflow user trap handler. If the operation does not result in an overflow, it writes the computed result to the destination, sets the appropriate flags in the FPSCR, and returns to user code.

## 23.3 Support code

The VFP11 coprocessor provides floating-point functionality through a combination of hardware and software support.

When an instruction bounces, software installed on the ARM Undefined Instruction vector determines why the VFP11 coprocessor rejected the instruction and takes appropriate remedial action. This software is called the *VFP support code*. The support code has two components:

- a library of routines that perform floating-point arithmetic functions
- a set of exception handlers that process exceptional conditions.

See *Application Note 98, VFP Support Code* for details of support code. Support code is provided with the RealView Compilation Tools, or for the ARM Developer Suite as an add-on downloadable from the ARM web site.

The remedial action is performed as follows:

1. The support code starts by reading the FPEXC register. If the EX flag, FPEXC[31], is set, a potential exception is present. If not, an illegal instruction is detected. See *Illegal instructions* on page 23-6.  
The contents of the FPEXC register must be retained throughout exception processing. Any VFP11 coprocessor activity might change FPEXC register bits from their state at the time of the exception.
2. The support code writes to the FPEXC register to clear the EX flag. Failure to do this can result in an infinite loop of exceptions when the support code next accesses the VFP11 hardware.
3. The support code reads the FPSCR to determine if IXE is set or not set. If IXE, FPSCR[12], is set, an inexact exception has occurred, that takes priority over other exceptions and is precise. Other exceptions are imprecise.
4. The support code reads either the FPINST register, or the instruction pointed to by r14-4, depending on whether the exception is precise or not, to determine the instruction that caused the potential exception.
5. The support code decodes the instruction in the FPINST register, reads its operands, including implicit information such as the rounding mode and vector length in the FPSCR register, executes the operation, and determines whether a floating-point exception occurred.
6. If no floating-point exception occurred, the support code writes the correct result of the operation and sets the appropriate flags in the FPSCR register.

If one or more floating-point exceptions occurred, but all of them were disabled, the support code determines the correct result of the instruction, writes it to the destination register, and sets the corresponding flags in the FPSCR register.

If one or more floating-point exceptions occurred, and at least one of them was enabled, the support code computes the intermediate result specified by the IEEE 754 standard, if required, and calls the user trap handler for that exception. The user trap handler can provide a result for the instruction and continue program execution, generate a signal or message to the operating system or the user, or terminate the program.

7. If the potentially exceptional instruction specified a short vector operation, the hardware does not execute any vector iterations after the one that encountered the potentially exceptional condition. The support code repeats steps 4 and 5 for any such iterations. For more details, see *Exception processing for CDP short vector instructions* on page 23-9.
8. If the FP2V flag, FPEXC[28], is set and IXE, FPSCR[12], is clear, the FPINST2 register contains another VFP instruction that was issued between the potentially exceptional instruction and the trigger instruction. This instruction is executed by the support code in the same manner as the instruction in the FPINST register. The FP2V flag must be cleared before returning to user code. See *Instruction registers, FPINST and FPINST2* on page 21-24 for more on FPINST2.
9. The support code finishes processing the potentially exceptional instruction and returns to the program containing the trigger instruction. The ARM11 processor refetches the trigger instruction from memory and reissues it to the VFP11 coprocessor. Unless another bounce occurs, the trigger instruction is executed. Returning in this fashion is called *retrying* the trigger instruction.

The support code can be written to use the VFP11 hardware for its internal calculations, provided that:

- recursive bounces are prevented or handled correctly
- care is taken to restore the state of the original program before returning to it.

Restoring the state of the original program can be difficult if the original program was executing in FIQ mode or in Undefined instruction mode. It is legitimate for support code to disable or restrict the use of VFP11 instructions in these two processor modes.

### 23.3.1 Illegal instructions

If there is not a potential floating-point exception from an earlier instruction, the current instruction can still be bounced if it is architecturally Undefined in some way. When this happens, the EX flag, FPEXC[31], is not set. The instruction that caused the bounce is contained in the memory word pointed to by r14\_undef - 4.

It is possible that both conditions for an instruction to be bounced occur simultaneously. This happens when an illegal instruction is encountered and there is also a potential floating-point exception from an earlier instruction. When this happens, the EX flag is set, and the support code processes the potential exception in the earlier instruction. If and when it returns, it causes the illegal instruction to be retried and the sequence of events described in the paragraph above occurs.

The following instruction types are architecturally Undefined (see *ARM Architecture Reference Manual, Rev E, Part C*):

- instructions with opcode bit combinations defined as reserved in the architecture specification
- load or store instructions with Undefined P, W, and U bit combinations
- FMRX/FMXR instructions to or from a control register that is not defined
- User mode FMRX/FMXR instructions to or from a control register that can be accessed only in a privileged mode
- double precision operations with odd register numbers.

Certain instruction types do not have architecturally-defined behavior and are Unpredictable:

- load or store multiple instructions with a transfer count of zero or greater than 32, and any combination of initial register and transfer count such that an attempt is made to transfer a register beyond S31 for single-precision transfers, or D15 for double-precision transfers
- a short vector instruction with a combination of precision, length, and stride that causes the vector to wrap around and make more than one access to the same register
- a short vector instruction with overlapping source and destination register addresses that are not exactly the same.

## 23.4 Exception processing

The ARM11/VFP11 interface specifies that an exceptional instruction that bounces to support code must signal on a subsequent coprocessor instruction. This is known as *imprecise exception handling*. It means that when the exception is processed, the VFP11 and ARM11 user states might be different from their states when the exceptional instruction executed. Parallel execution of VFP11 CDP instructions and data transfer instructions enables the VFP11 and ARM11 register files and memory to be modified outside of the program order.

### 23.4.1 Determination of the trigger instruction

The issue timing of VFP11 instructions affects the determination of the trigger instruction. The last iteration of a short vector CDP can be followed in the next cycle by a second CDP instruction. If there is no hazard, the VFP11 coprocessor accepts the second CDP instruction before the exception status of the last iteration of the short vector CDP is known. The second CDP instruction is said to be in the *pretrigger slot* and is retained in the FPINST2 register for the support code.

The following rules determine which instruction is the trigger instruction:

- The first nonserializing instruction after the exceptional condition has been detected is the trigger instruction.
- An instruction that accesses the FPSCR register in any processor mode is a trigger instruction.
- An instruction that accesses the FPEXC, FPINST, or FPINST2 register in a privileged mode is not a trigger instruction.
- An instruction that accesses the FPSID register in any mode is not a trigger instruction.
- A data processing instruction that reaches the LS pipeline Execute stage or a CDP instruction that reaches the FMAC or DS pipeline E1 stage is not the trigger instruction. There can be several of these if the exceptional instruction is a sufficiently long short vector instruction, and the exception is detected on a later iteration.

### 23.4.2 Exception processing for CDP scalar instructions

When the VFP11 coprocessor detects an exceptional scalar CDP instruction, it loads the FPINST register with the instruction word for the exceptional instruction and flags the condition in the FPEXC register. It blocks the exceptional instruction from further execution and completes any instructions currently executing in the FMAc and DS pipelines.

It then examines the pipeline for a trigger instruction:

- If there is a VFP CDP instruction or a load or store instruction in the VFP11 Issue stage, it is the trigger instruction and is bounced in the cycle after the exception is detected.
- If there is no VFP instruction in the VFP11 Issue stage, the VFP11 coprocessor waits until one is issued. The next VFP instruction is the trigger instruction and is bounced.

When the ARM11 processor returns from exception processing, it retries the trigger instruction.

### 23.4.3 Exception processing for CDP short vector instructions

For short vector instructions, any iteration might be exceptional. If an exceptional condition is detected for a vector iteration, the vector iterations issued before the exceptional iteration are permitted to complete and retire.

When a short vector iteration is found to be potentially exceptional, the following operations occur:

1. The EX flag, FPEXC[31], is set.
2. The source and destination register addresses are modified in the instruction word to point to the source and destination registers of the potentially exceptional iteration.
3. The FPINST register is loaded with the operation instruction word.
4. The VECITR field, FPEXC[10:8], is written with the number of iterations remaining after the potentially exceptional iteration.
5. The exceptional condition flags are set in the FPEXC.

23.4.4 Examples of exception detection for vector instructions

In Example 23-1, the FMULD instruction is a short vector operation with b011 in the LEN field for a length of four iterations and b00 in the STRIDE field for a vector stride of one. A potential Underflow exception is detected on the third iteration.

Example 23-1 Exceptional short vector FMULD followed by load/store instructions

|                   |                                                      |
|-------------------|------------------------------------------------------|
| FMULD D8, D12, D8 | ; Short vector double-precision multiply of length 4 |
| FLDD D0, [R5]     | ; Load of 1 double-precision register                |
| FSTMS R3, {S2-S9} | ; Store multiple of 8 single-precision registers     |
| FLDS S8, [R9]     | ; Load of 1 single-precision register                |

A double-precision multiply requires two cycles in the Execute 2 stage. The exception on the third iteration is detected in cycle 8. Before the FMULD exception is detected, the FLDD enters the Decode stage in cycle 2, and the FSTMS enters the Decode stage in cycle 3. The FLDD and the FSTMS complete execution and retire. The FLDS stalls in the Decode stage because of a resource conflict with the FSTMS and is the trigger instruction. It is bounced in cycle 9 and can be retried after exception processing. FPINST2 is invalid, and the FP2V flag, FPEXC[28], is not set.

Table 23-1 shows the pipeline stages for Example 23-1.

Table 23-1 Exceptional short vector FMULD followed by load/store instructions

| Instruction       | Instruction cycle number |   |    |    |    |    |    |    |   |    |    |    |    |    |    |    |
|-------------------|--------------------------|---|----|----|----|----|----|----|---|----|----|----|----|----|----|----|
|                   | 1                        | 2 | 3  | 4  | 5  | 6  | 7  | 8  | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
| FMULD D8, D12, D8 | D                        | I | E1 | E2 | E1 | E2 | E1 | E2 | - | -  | -  | -  | -  | -  | -  | -  |
| FLDD D0, [R5]     | -                        | D | I  | E  | M1 | M2 | W  | -  | - | -  | -  | -  | -  | -  | -  | -  |
| FSTMS R3, {S2-S9} | -                        | - | D  | I  | E  | M1 | M2 | W  | W | W  | W  | -  | -  | -  | -  | -  |

After exception processing begins, the FPEXC register fields contain the following:

|        |     |                                                        |
|--------|-----|--------------------------------------------------------|
| EX     | 1   | The VFP11 coprocessor is in the exceptional state.     |
| EN     | 1   |                                                        |
| FP2V   | 0   | FPINST2 does not contain a valid instruction.          |
| VECITR | 000 | One iteration remains after the exceptional iteration. |
| INV    | 0   |                                                        |
| UFC    | 1   | Exception detected is a potential underflow.           |
| OFC    | 0   |                                                        |

IOC      0

The FPINST register contains the FMULD instruction with the following fields modified to reflect the register address of the third iteration.

|      |        |                                                        |
|------|--------|--------------------------------------------------------|
| Fd/D | 1010/0 | Destination of the third exceptional iteration is D10. |
| Fm/M | 1010/0 | Fm source of the third exceptional iteration is D10.   |
| Fn/N | 1110/0 | Fn source of the third exceptional iteration is D14.   |

The FPINST2 register contains invalid data.

In Example 23-2, the first FADDS is a short vector operation with b001 in the LEN field for a vector length of two iterations and b00 in the STRIDE field for a vector stride of one. A potential Invalid Operation exception is detected in the second iteration. The second FADDS progresses to the Execute 1 stage and is captured in the FPINST2 register with the condition field changed to AL, the FP2V flag set, and is not the trigger instruction. The FMULS is the trigger instruction and bounces in cycle 6. It can be retried after exception processing.

#### Example 23-2 Exceptional short-vector FADDS with a FADDS in the pretrigger slot

---

|                     |                                           |
|---------------------|-------------------------------------------|
| FADDS S24, S26, S28 | ; Vector single-precision add of length 2 |
| FADDS S3, S4, S5    | ; Scalar single-precision add             |
| FMULS S12, S16, S16 | ; Short vector single-precision multiply  |

---

Table 23-2 shows the pipeline stages for Example 23-2.

**Table 23-2 Exceptional short vector FADDS with a FADDS in the pretrigger slot**

| Instruction         | Instruction cycle number |   |    |    |    |   |   |   |   |    |    |    |    |    |    |    |
|---------------------|--------------------------|---|----|----|----|---|---|---|---|----|----|----|----|----|----|----|
|                     | 1                        | 2 | 3  | 4  | 5  | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
| FADDS S24, S26, S28 | D                        | I | E1 | E1 | E2 | - | - | - | - | -  | -  | -  | -  | -  | -  | -  |
| FADDS S3, S4, S5    | -                        | D | D  | I  | E1 | - | - | - | - | -  | -  | -  | -  | -  | -  | -  |
| FMULS S12, S16, S16 | -                        | - | -  | D  | I  | * | - | - | - | -  | -  | -  | -  | -  | -  | -  |

After exception processing begins, the FPEXC register fields contains the following:

|        |     |                                                      |
|--------|-----|------------------------------------------------------|
| EX     | 1   | The VFP11 coprocessor is in the exceptional state.   |
| EN     | 1   |                                                      |
| FP2V   | 1   | FPINST2 contains a valid instruction.                |
| VECITR | 111 | No iterations remaining after exceptional iteration. |
| INV    | 0   |                                                      |

UFC     0  
OFC     0  
IOC     1    Exception detected is a potential invalid operation.

The FPINSTregistercontains the FADDS instruction with the following fields modified to reflect the register address of the second iteration:

Fd/D    1100/1    Destination is of the second exceptional iteration is S25.  
Fn/N    1101/1    Fn source is of the second exceptional iteration is S27.  
Fm/M    1110/1    Fm source is of the second exceptional iteration is S29.

The FPINST2 register contains the instruction word for the second FADDS with the condition field changed to AL.

In Example 23-3, FADDD is a short vector instruction with b011 in the LEN field for a vector length of four iterations and b00 in the STRIDE field for a vector stride of one. It has a potential Overflow exception in the first iteration, detected in cycle 4. The following FMACS is stalled in the Decode stage. The FMACS is the trigger instruction and can be retried after exception processing. FPINST2 is invalid and the FP2V flag is not set.

**Example 23-3 Exceptional short vector FADDD with an FMACS trigger instruction**

FADDD D4, D4, D12    ; Short vector double-precision add of length 4  
FMACS S0, S3, S2     ; Scalar single-precision mac

Table 23-3 shows the pipeline stages for Example 23-3.

**Table 23-3 Exceptional short vector FADDD with an FMACS trigger instruction**

| Instruction cycle number |   |   |    |    |   |   |   |   |   |    |    |    |    |    |    |    |
|--------------------------|---|---|----|----|---|---|---|---|---|----|----|----|----|----|----|----|
| Instruction              | 1 | 2 | 3  | 4  | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
| FADDD D4, D4, D12        | D | I | E1 | E2 | - | - | - | - | - | -  | -  | -  | -  | -  | -  | -  |
| FMACS S0, S3, S2         | - | D | D  | I  | * |   |   |   | - | -  | -  | -  | -  | -  | -  | -  |

After exception processing begins, the FPEXC register fields contain the following:

EX       1    The VFP11 coprocessor is in the exceptional state.  
EN       1  
FP2V     0    FPINST2 does not contain a valid instruction.  
VECITR   010 Three iterations remain.  
INV       0  
UFC       0

OFC     1    Exception detected is a potential overflow.  
 IOC     0

The FPINSTregister contains the FADDD instruction with the following fields modified to reflect the register address of the first iteration:

Fd/D    0100/0    Destination of exceptional iteration is D4.  
 Fn/N    0100/0    Fn source of the first exceptional iteration is D4.  
 Fm/M    1100/0    Fm source of the first exceptional iteration is D12.

FPINST2 contains invalid data.

## 23.5 Input Subnormal exception

The IDC flag, FPSCR[7], is set whenever a floating-point operand is subnormal. The behavior of the VFP11 coprocessor with a subnormal input operand is a function of the FZ bit, FPSCR[24]. If FZ is not set, the VFP11 coprocessor bounces on the presence of a subnormal input. If FZ is set, the IDE bit, FPSCR[15], determines whether a bounce occurs.

### 23.5.1 Exception enabled

Setting the IDE bit enables Input Subnormal exceptions. An Input Subnormal exception sets the EX flag, FPEXC[31], the INV flag, FPEXC[7], and calls the Input Subnormal user trap handler. The source and destination registers for the instruction are unchanged in the VFP11 register file.

### 23.5.2 Exception disabled

Clearing the IDE bit disables Input Subnormal exceptions. In flush-to-zero mode, the result of the operation, with the subnormal input replaced with a positive zero, is completed and written to the register file. The IDC flag, FPSCR[7], is set.

## 23.6 Invalid Operation exception

An operation is *invalid* if the result cannot be represented, or if the result is not defined.

Table 23-4 shows the operand combinations that produce Invalid Operation exceptions. In addition to the conditions in Table 23-4, any CDP instruction other than FCPY, FNEG, or FABS causes an Invalid Operation exception if one or more of its operands is an SNaN (see Table 20-1 on page 20-6).

**Table 23-4 Possible Invalid Operation exceptions**

| Instruction  | Invalid Operation exceptions                                                                                                                                                                                                                                                                                               |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FADD         | $(+\infty) + (-\infty)$ or $(-\infty) + (+\infty)$ .                                                                                                                                                                                                                                                                       |
| FSUB         | $(+\infty) - (+\infty)$ or $(-\infty) - (-\infty)$ .                                                                                                                                                                                                                                                                       |
| FCMPE/FCMPEZ | Any NaN operand                                                                                                                                                                                                                                                                                                            |
| FMUL/FNMUL   | Zero $\downarrow$ $\pm\infty$ or $\pm\infty \downarrow$ zero. <sup>a</sup>                                                                                                                                                                                                                                                 |
| FDIV         | Zero/zero or infinity/infinity. <sup>a</sup>                                                                                                                                                                                                                                                                               |
| FMAC/FNMAC   | Any condition that can cause an Invalid Operation exception for FMUL or FADD can cause an Invalid Operation exception for FMAC and FNMAC. The product generated by the FMAC or FNMAC multiply operation is considered in the detection of the Invalid Operation exception for the subsequent sum operation.                |
| FMSC/FNMSC   | Any of the conditions that can cause an Invalid Operation exception for FMUL or FSUB can cause an Invalid Operation exception for FMSC and FNMSC. The product generated by the FMSC or FNMSC multiply operation is considered in the detection of the Invalid Operation exception for the subsequent difference operation. |
| FSQRT        | Source is less than 0.                                                                                                                                                                                                                                                                                                     |
| FTOUI        | Rounded result would lie outside the range $0 \leq \text{result} < 2^{32}$ .                                                                                                                                                                                                                                               |
| FTOSI        | Rounded result would lie outside the range $-2^{31} \leq \text{result} < 2^{31}$ .                                                                                                                                                                                                                                         |

a. In flush-to-zero mode, a subnormal input is treated as a positive zero for detecting an Invalid Operation exception.

### 23.6.1 Exception enabled

Setting the IOE bit, FPSCR[8], enables Invalid Operation exceptions.

The VFP11 coprocessor causes a bounce to support code for all the invalid operation conditions listed in Table 23-4 on page 23-15. Any arithmetic operation involving an SNaN also causes a bounce to support code. The VFP11 coprocessor detects most Invalid Operations exceptions conclusively but some are detected based on the possibility of an invalid operation. The potentially invalid operations are:

- FTOUI with a negative input. A small negative input might round to a zero, which is not an invalid condition.
- A float-to-integer conversion with a maximum exponent for the destination integer and any rounding mode other than round-towards-zero. The impact of rounding is unknown in the Execute 1 stage.
- An FMAC family operation with an infinity in the A operand and a potential product overflow when an infinity with the sign of the product would result in an invalid condition.

When the VFP11 coprocessor detects a potentially invalid condition, the EX flag, FPEXC[31], and the IOC flag, FPEXC[0], are set. The IOC flag in the FPSCR register, FPSCR[0], is not set by the hardware and must be set by the support code before calling the Invalid Operation user trap handler.

The support code determines the exception status of all bounced instructions. If an invalid condition exists, the Invalid Operation user trap handler is called. The source and destination registers for the instruction are valid in the VFP11 register file.

## 23.6.2 Exception disabled

If the IOE bit is not set, the VFP11 coprocessor writes a default NaN into the destination register for all operations except integer conversion operations.

Conversion of a floating-point value that is outside the range of the destination integer is an invalid condition rather than an overflow condition. When an invalid condition exists for a float-to-integer conversion, the VFP11 coprocessor delivers a default result to the destination register and sets the IOC flag, FPSCR[0]. Table 23-5 on page 23-17 shows the default results for input values after rounding.

If the VFP11 coprocessor is not in default NaN mode, an arithmetic instruction with an SNaN operand sets the IOC flag and causes a bounce to support code.

### ———— Note —————

A negative input to an unsigned conversion that does not round to a true zero in the conversion process sets the IOC flag, FPEXC[0].

Table 23-5 Default results for invalid conversion inputs

| Input value after rounding | FTOUIS and FTOUID |                     | FTOSIS and FTOSID |                     |
|----------------------------|-------------------|---------------------|-------------------|---------------------|
|                            | Result            | FPSCR IOC flag set? | Result            | FPSCR IOC flag set? |
| $x \geq 2^{32}$            | 0xFFFFFFFF        | Yes                 | 0x7FFFFFFF        | Yes                 |
| $2^{31} \leq x < 2^{32}$   | Integer           | No                  | 0x7FFFFFFF        | Yes                 |
| $0 \leq x < 2^{31}$        | Integer           | No                  | Integer           | No                  |
| $0 \geq x \geq -2^{31}$    | 0x00000000        | Yes                 | Integer           | No                  |
| $x < -2^{31}$              | 0x00000000        | Yes                 | 0x80000000        | Yes                 |
| NaN                        | 0x00000000        | Yes                 | 0x00000000        | Yes                 |
| +infinity                  | 0xFFFFFFFF        | Yes                 | 0x7FFFFFFF        | Yes                 |
| -infinity                  | 0x00000000        | Yes                 | 0x80000000        | Yes                 |

## 23.7 Division by Zero exception

The Division by Zero exception is generated for a division by zero of a normal or subnormal value. In flush-to-zero mode, a subnormal input is treated as a positive zero for detection of a division by zero. What happens depends on whether or not the Invalid Operation exception is enabled.

### 23.7.1 Exception enabled

If the DZE bit, FPSCR[9], is set, the Division by Zero user trap handler is called. The source and destination registers for the instruction are unchanged in the VFP11 register file.

### 23.7.2 Exception disabled

Clearing the DZE bit disables Division by Zero exceptions. A correctly signed infinity is written to the destination register, and the DZC flag, FPSCR[1], is set.

## 23.8 Overflow exception

When the OFE bit, FPSCR[10], is set, the hardware detects overflow pessimistically based on the preliminary calculation of the final exponent value. If the OFE bit is not set, the hardware detects overflow conclusively.

### 23.8.1 Exception enabled

Setting the OFE bit enables overflow exceptions. The VFP11 coprocessor detects most overflow conditions conclusively, but it detects some based on the possibility of overflow. The initial computation of the result exponent might be the maximum exponent or one less than the maximum exponent of the destination precision. Then the possibility of overflow because of significand overflow or rounding exists, but cannot be known in the first Execute stage. The VFP11 coprocessor bounces on such cases and uses the support code to determine the exceptional status of the operation. If there is no overflow, the support code writes the computed result to the destination register and does not set the OFC flag, FPSCR[2]. If there is an overflow, the intermediate result is written to the destination register, OFC is set, and the Overflow user trap handler is called. The support code sets or clears the IXC flag, FPSCR[4], as appropriate.

When the VFP11 coprocessor detects a potential overflow condition, the EX flag, FPEXC[31], and the OFC flag, FPEXC[2], are set. The OFC flag in the FPSCR register, FPSCR[2], is not set by the hardware and must be set by the support code before calling the user trap handler. The source and destination registers for the instruction are unchanged in the VFP11 register file. See *Arithmetic exceptions* on page 23-25 for the conditions that cause an overflow bounce.

### 23.8.2 Exception disabled

Clearing the OFE bit disables overflow exceptions. A correctly signed infinity or the largest signed finite number for the destination precision is written to the destination register as Table 23-6 on page 23-20 shows. The OFC and IXC flags, FPSCR[2] and FPSCR[4], are set.

Table 23-6 Rounding mode overflow results

| Rounding mode                | Result                                                                                                        |
|------------------------------|---------------------------------------------------------------------------------------------------------------|
| Round to nearest             | Infinity, with the sign of the intermediate result.                                                           |
| Round towards zero           | Largest magnitude value for the destination size, with the sign of the intermediate result.                   |
| Round towards plus infinity  | Positive infinity if positive overflow. Largest negative value for the destination size if negative overflow. |
| Round towards minus infinity | Largest positive value for the destination size if positive overflow. Negative infinity if negative overflow. |

## 23.9 Underflow exception

Underflow is detected pessimistically in non-RunFast mode. If the potential underflow is confirmed by the support code for an operation with a floating-point result, an underflow exception is generated. How this is confirmed depends on whether the VFP11 coprocessor is in flush-to-zero mode.

If the FZ bit is set, all underflowing results are forced to a positive signed zero and written to the destination register. The UFC flag is set in the FPSCR. No trap is taken. If the Underflow exception enable bit is set, it is ignored.

If the FZ bit is not set what happens next depends on whether the Underflow exception is enabled.

### 23.9.1 Exception enabled

Setting the UFE bit, FPSCR[11], enables Underflow exceptions. The VFP11 coprocessor detects most underflow conditions conclusively, but it detects some based on the possibility of an underflow. The initial computation of the result exponent might be below a threshold for the destination precision. In this case, the possibility of underflow because of massive cancellation exists, but cannot be known in the first Execute stage. The VFP11 coprocessor bounces on such cases and uses the support code to determine the exceptional status of the operation. Underflow is confirmed if the result of the operation after rounding is less in magnitude than the smallest normalized number in the destination format. If there is no underflow, either catastrophic or to a subnormal result, the support code writes the computed result to the destination register and returns without setting the UFC flag, FPSCR[3]. If there is underflow, regardless of any accuracy loss, the intermediate result is written to the destination register, UFC is set, and the Underflow user trap handler is called. The support code sets or clears the IXC flag, FPSCR[4], as appropriate.

When the VFP11 coprocessor detects a potential underflow condition, the EX flag, FPEXC[31], and the UFC flag, FPEXC[3], are set. The UFC flag in the FPSCR register is not set by the hardware and must be set by the support code before calling the user trap handler. The source and destination registers for the instruction are valid in the VFP11 register file. See *Arithmetic exceptions* on page 23-25 for the conditions that cause an underflow bounce.

### 23.9.2 Exception disabled

Clearing the UFE bit, FPSCR[11], disables Underflow exceptions. When the FZ bit, FPSCR[24], is not set, the VFP11 coprocessor bounces on potential underflow cases in the same fashion as described in *Exception enabled*. The correct result is written to the destination register, setting the appropriate exception flags.

When the FZ bit is set, the VFP11 coprocessor makes the determination of underflow before rounding and flushes any result that underflows. A result that underflows returns a positive zero to the destination register and sets the UFC flag, FPSCR[3].

———— **Note** ————

The determination of an underflow condition in flush-to-zero mode is made before rounding rather than after. This means that the VFP11 coprocessor might not return the minimum normal value when rounding would have produced it. Instead, it flushes to zero an intermediate value with the minimum exponent for the destination precision, a fraction of all ones, and a round increment. If the intermediate value was the minimum normal value before the underflow condition test is made, it is not flushed to zero.

---

## 23.10 Inexact exception

The result of an arithmetic operation on two floating-point values can have more significant bits than the destination register can contain. When this happens, the result is rounded to a value that the destination register can hold and is said to be *inexact*.

The Inexact exception occurs whenever:

- a result is not equal to the computed result before rounding
- an untrapped Overflow exception occurs
- an untrapped Underflow exception occurs, and there is loss of accuracy.

---

### Note

The Inexact exception occurs frequently in normal floating-point calculations and does not indicate a significant numerical error except in some specialized applications. Enabling the Inexact exception by setting the IXE bit, FPSCR[12], can significantly reduce the performance of the VFP11 coprocessor.

---

The VFP11 coprocessor handles the Inexact exception differently from the other floating-point exceptions. It has no mechanism for reporting inexact results to the software, but can handle the exception without software intervention as long as the IXE bit, FPSCR[12], is cleared, disabling Inexact exceptions.

### 23.10.1 Exception enabled

If the IXE bit, FPSCR[12], is set, all CDP instructions are bounced to the support code without any attempt to perform the calculation. The support code is then responsible for performing the calculation, determining if any exceptions have taken place, and handling them appropriately. If the support code detects an Inexact exception, it calls the Inexact user trap handler.

---

### Note

- The inexact exception takes priority over all other exceptions.
  - The inexact exception is taken precisely, unlike other exceptions. This means that when a CDP is bounced, because it is potentially imprecise, the instruction is at the address pointed to by r14-4 and is not stored in the FPINST register. There is never a pre-trigger instruction in the FPINST2 register.
- 

### 23.10.2 Exception disabled

If the IXE bit, FPSCR[12], is not set, the VFP11 coprocessor writes the result to the destination register and sets the IXC flag, FPSCR[4].

## 23.11 Input exceptions

The VFP11 hardware processes most input operands without support code assistance. However, the hardware is incapable of processing some operands and bounces to support code to process the instruction. An arithmetic operation bounces with an Input exception when it has either of the following:

- a NaN operand or operands, and default NaN mode is not enabled
- a subnormal operand or operands, and flush-to-zero mode is not enabled.

---

**Note**

In default NaN mode, an SNaN input to an arithmetic operation causes an Invalid Operation exception. When the IOE bit, FPSCR[8], is set, the instruction bounces to the Invalid Operation user trap handler. When the IOE bit is clear, and the VFP11 coprocessor is not in default NaN mode, the instruction bounces to the support code.

---

## 23.12 Arithmetic exceptions

This section describes the conditions under which the VFP11 coprocessor bounces an arithmetic instruction based on the potential for the exception. It is the task of the support code to determine the actual exception status of the instruction. The support code must return either the result and appropriate exception status bits, or the intermediate result and a call to a user trap handler.

The following sections describe the circumstances in which arithmetic exceptions occur:

- *FADD and FSUB*
- *FCMP, FCMPZ, FCMPE, and FCMPEZ* on page 23-27
- *FMUL and FNMUL* on page 23-27
- *FMAC, FMSC, FNMAC, and FNMSC* on page 23-29
- *FDIV* on page 23-29
- *FSQRT* on page 23-30
- *FCPY, FABS, and FNEG* on page 23-30
- *FCVTDS and FCVTSD* on page 23-31
- *FUITO and FSITO* on page 23-31
- *FTOUI, FTOUIZ, FTOSI, and FTOSIZ* on page 23-31.

### 23.12.1 FADD and FSUB

In an addition or subtraction, the exponent is initially the larger of the two input exponents. For clarity, we define the operation as a *Like-Signed Addition* (LSA) or an *Unlike-Signed Addition* (USA). Table 23-7 specifies how this distinction is made. In the table, + indicates a positive operand, and - indicates a negative operand.

**Table 23-7 LSA and USA determination**

| Instruction | Operand A sign | Operand B sign | Operation type |
|-------------|----------------|----------------|----------------|
| FADD        | +              | +              | LSA            |
| FADD        | +              | -              | USA            |
| FADD        | -              | +              | USA            |
| FADD        | -              | -              | LSA            |
| FSUB        | +              | +              | USA            |

**Table 23-7 LSA and USA determination (continued)**

| Instruction | Operand A sign | Operand B sign | Operation type |
|-------------|----------------|----------------|----------------|
| FSUB        | +              | -              | LSA            |
| FSUB        | -              | +              | LSA            |
| FSUB        | -              | -              | USA            |

Because it is possible for an LSA operation to cause the exponent to be incremented if the significand overflows, overflow bounce ranges for an LSA are more pessimistic than they are for a USA. The LSA ranges are made slightly more pessimistic to incorporate FMAC instructions (see *FMAC*, *FMSC*, *FNMAC*, and *FNMSC* on page 23-29).

Underflow bounce ranges for a USA are more pessimistic than they are for an LSA. This is to accommodate a massive cancellation in which the result exponent is smaller than the larger operand exponent by as much as the length of the significand. The overflow range for a USA is slightly pessimistic (it is set to the LSA overflow range) to reduce the number of logic terms. Table 23-8 shows the USA and LSA values and conditions. The exponent values in Table 23-8 are in biased format.

**Table 23-8 FADD family bounce thresholds**

| Initial result exponent value |                 |                               | Condition when not in flush-to-zero mode |        |
|-------------------------------|-----------------|-------------------------------|------------------------------------------|--------|
| DP <sup>a</sup>               | SP <sup>b</sup> | Float value                   | SP                                       | DP     |
| >0x7FF                        | -               | DP overflow                   | -                                        | Bounce |
| 0x7FF                         | -               | DP overflow, NaN, or infinity | -                                        | Bounce |
| 0x7FE                         | -               | DP overflow                   | -                                        | Bounce |
| 0x7FD                         | -               | DP overflow                   | -                                        | Bounce |
| 0x7FC                         | -               | DP normal                     | -                                        | Normal |
| >0x47F                        | >0xFF           | SP overflow                   | Bounce                                   | Normal |

| 0x380                         | 0x00            | SP subnormal       | Bounce                                   | Normal                        |
| <0x380                        | <0x00           | SP underflow       | Bounce                                   | Normal                        |
| 0x040                         | -               | DP normal (USA)    | -                                        | Normal (LSA) or minimum (USA) |
| 0x03F                         | -               | DP underflow (USA) | -                                        | Normal (LSA) or bounce (USA)  |
| 0x001                         | -               | DP normal (LSA)    | -                                        | Minimum (LSA) or bounce (USA) |
| 0x000                         | -               | DP subnormal       | -                                        | Bounce                        |

a. DP = double-precision.

b. SP = single-precision.

### 23.12.2 FCMP, FCMPZ, FCMPE, and FCMPEZ

Compare operations do not generate potential exceptions.

### 23.12.3 FMUL and FNMUL

Detection of a potential exception is based on the initial product exponent, which is the sum of the multiplicand and multiplier exponents. Table 23-9 on page 23-28 shows the result for specific values of the initial product exponent. The exponent values in Table 23-9 on page 23-28 are in biased format. The exponent can be incremented by a significand overflow condition, which is the cause for the additional bounce values near

the real overflow threshold. The one additional value in the bounce range makes the FMUL and FNMUL overflow detection ranges identical to those in Table 23-8 on page 23-26.

**Table 23-9 FMUL family bounce thresholds**

| Initial product exponent value |                 |                    | Condition in full-compliance mode |        |
|--------------------------------|-----------------|--------------------|-----------------------------------|--------|
| DP <sup>a</sup>                | SP <sup>b</sup> | Float value        | SP                                | DP     |
| >0x7FF                         | -               | DP overflow        | -                                 | Bounce |
| 0x7FF                          | -               | DP NaN or infinity | -                                 | Bounce |
| 0x7FE                          | -               | DP maximum normal  | -                                 | Bounce |
| 0x7FD                          | -               | DP normal          | -                                 | Bounce |
| 0x7FC                          | -               | DP normal          | -                                 | Normal |
| >0x47F                         | >0xFF           | SP overflow        | Bounce                            | Normal |
| 0x47F                          | 0xFF            | SP NaN or infinity | Bounce                            | Normal |
| 0x47E                          | 0xFE            | SP maximum normal  | Bounce                            | Normal |
| 0x47D                          | 0xFD            | SP normal          | Bounce                            | Normal |
| 0x47C                          | 0xFC            | SP normal          | Normal                            | Normal |
| 0x3FF                          | 0x7F            | e = 0 bias value   | Normal                            | Normal |
| 0x381                          | 0x01            | SP normal          | Normal                            | Normal |
| 0x380                          | 0x00            | SP subnormal       | Bounce                            | Normal |
| <0x380                         | <0x00           | SP underflow       | Bounce                            | Normal |
| 0x001                          | -               | DP normal          | -                                 | Normal |
| 0x000                          | -               | DP subnormal       | -                                 | Bounce |
| <0x000                         | -               | DP underflow       | -                                 | Bounce |

a. DP = double-precision.

b. SP = single-precision.

### 23.12.4 FMAC, FMSC, FNMAC, and FNMSC

The FMAC family of operations adds to the potential overflow range by generating significand values from zero up to but not including four. In this case it is possible for the final exponent to require incrementing by two to normalize the significand.

The bounce thresholds for the FADD family in Table 23-8 on page 23-26 and for the FMUL family in Table 23-9 on page 23-28 incorporate this additional factor. Those ranges are used to detect potential exceptions for the FMAC family.

### 23.12.5 FDIV

The thresholds for divide are simple and based only on the difference of the exponents of the dividend and the divisor. It is not possible in a divide operation for the significand to overflow and cause an increment of the exponent. However, it is possible for the significand to require a single bit left shift and the exponent to be decremented for normalization. To reduce logic complexity, the overflow ranges are the same as those of the LSA operations in *FADD* and *FSUB* on page 23-25. The underflow ranges include the minimum normal exponent, 0x01 for single-precision and 0x001 for double-precision. Table 23-10 shows the FDIV bounce thresholds. The exponent values shown in Table 23-10 are in biased format.

**Table 23-10 FDIV bounce thresholds**

| Initial quotient exponent value |                 |                    | Condition in full-compliance mode |        |
|---------------------------------|-----------------|--------------------|-----------------------------------|--------|
| DP <sup>a</sup>                 | SP <sup>b</sup> | Float value        | SP                                | DP     |
| >0x7FF                          | -               | DP overflow        | -                                 | Bounce |
| 0x7FF                           | -               | DP NaN or infinity | -                                 | Bounce |
| 0x7FE                           | -               | DP maximum normal  | -                                 | Bounce |
| 0x7FD                           | -               | DP normal          | -                                 | Bounce |
| 0x7FC                           | -               | DP normal          | -                                 | Normal |
| >0x47F                          | >0xFF           | SP overflow        | Bounce                            | Normal |
| 0x47F                           | 0xFF            | SP NaN or infinity | Bounce                            | Normal |
| 0x47E                           | 0xFE            | SP maximum normal  | Bounce                            | Normal |
| 0x47D                           | 0xFD            | SP normal          | Bounce                            | Normal |
| 0x47C                           | 0xFC            | SP normal          | Normal                            | Normal |

Table 23-10 FDIV bounce thresholds (continued)

| Initial quotient<br>exponent value |                 |                  | Condition in full-compliance mode |        |
|------------------------------------|-----------------|------------------|-----------------------------------|--------|

| <0x380                             | <0x00           | SP underflow     | Bounce                            | Normal |
| 0x002                              | -               | DP normal        | -                                 | Normal |
| 0x001                              | -               | DP normal        | -                                 | Bounce |
| 0x000                              | -               | DP subnormal     | -                                 | Bounce |
| <0x000                             | -               | DP underflow     | -                                 | Bounce |

- a. DP = double-precision.
- b. SP = single-precision.

23.12.6 FSQRT

It is not possible for FSQRT to overflow or underflow.

23.12.7 FCPY, FABS, and FNEG

It is not possible for FCPY, FABS, or FNEG to bounce for any operand.

### 23.12.8 FCVTDS and FCVTSD

Only the FCVTSD operation is capable of overflow or underflow. To reduce logic complexity, the overflow ranges are the same as the LSA ranges. Table 23-11 lists the FCVTSD bounce conditions. The exponent values shown in Table 23-11 are in biased format.

**Table 23-11 FCVTSD bounce thresholds**

| Double-precision operand exponent value | Float value              | FCVTSD condition in full-compliance mode |
|-----------------------------------------|--------------------------|------------------------------------------|
| >0x47F                                  | SP <sup>a</sup> overflow | Bounce                                   |
| 0x47F                                   | SP NaN or infinity       | Bounce                                   |
| 0x47E                                   | SP maximum normal        | Bounce                                   |
| 0x47D                                   | SP normal                | Bounce                                   |
| 0x47C                                   | SP normal                | Normal                                   |
| 0x3FF                                   | e = 0 bias value         | Normal                                   |
| 0x381                                   | SP normal                | Normal                                   |
| 0x380                                   | SP subnormal             | Bounce                                   |
| <0x380                                  | SP underflow             | Bounce                                   |

a. SP = single-precision.

### 23.12.9 FUITO and FSITO

It is not possible to generate overflow or underflow in an integer-to-float conversion.

### 23.12.10 FTOUI, FTOUIZ, FTOSI, and FTOSIZ

Float-to-integer conversions generate Invalid Operation exceptions rather than Overflow or Underflow exceptions. To support signed conversions with round-towards-zero rounding in the maximum range possible for C, C++, and Java compiled code, the thresholds for pessimistic bouncing are different for the various rounding modes.

Table 23-12 on page 23-32 and Table 23-13 on page 23-33 use the following notation:

In the *VFP Response* column, the response notations are:

**all**                    These input values are bounced for all rounding modes.

|            |                                                                                                          |
|------------|----------------------------------------------------------------------------------------------------------|
| <b>S</b>   | These input values are bounced for signed conversions in all rounding modes.                             |
| <b>SnZ</b> | These input values are bounced for signed conversions in all rounding modes except round-towards-zero.   |
| <b>U</b>   | These input values are bounced for unsigned conversions in all rounding modes.                           |
| <b>UnZ</b> | These input values are bounced for unsigned conversions in all rounding modes except round-towards-zero. |

In the *Unsigned results* and *Signed results* columns, the rounding mode notations are:

|          |                                    |
|----------|------------------------------------|
| <b>N</b> | Round-to-nearest mode.             |
| <b>P</b> | Round-towards-plus-infinity mode.  |
| <b>M</b> | Round-towards-minus infinity mode. |
| <b>Z</b> | Round-towards-zero mode.           |

Table 23-12 shows the single-precision float-to-integer bounce range and the results returned for exceptional conditions. The exponent values shown in Table 23-12 are in biased format.

**Table 23-12 Single-precision float-to-integer bounce thresholds and stored results**

| Floating-point value     | Integer value                                       | Unsigned result            | Status               | Signed result              | Status  | VFP11 response |
|--------------------------|-----------------------------------------------------|----------------------------|----------------------|----------------------------|---------|----------------|

a. max DP = maximum double-precision.

b. A negative input value that rounds to a zero result returns zero and is not invalid.

# Appendix A

## Processor Signal Descriptions

This appendix lists and describes the processor signals. It contains the following sections:

- *Global signals* on page A-2
- *Configuration signals* on page A-3
- *Interrupt signals (including VIC interface signals)* on page A-4
- *AXI interface signals* on page A-5
- *Instruction TCM Interface* on page A-10
- *Data TCM Interface* on page A-11
- *Coprocessor interface signals* on page A-12
- *Debug interface signals (including JTAG)* on page A-14
- *ETM interface signals* on page A-15
- *Test signals* on page A-16.

---

### Note

---

The output signals shown in Table A-1 on page A-2 to Table A-13 on page A-16 are set to 0 on reset unless otherwise stated.

---

A.1 Global signals

Table A-1 lists the ARM1156T2F-S global signals.

Free clocks are the free running clocks with minimal insertion delay for clocking the clock gating circuits. Free clocks must be balanced with the incoming clock signal, but not with the clocks clocking the core logic.

Table A-1 Global signals

| Name         | Direction | Description                                                                 |
|--------------|-----------|-----------------------------------------------------------------------------|
| CLKIN        | Input     | Core clock                                                                  |
| DBGTCKEN     | Input     | Clock enable for debug                                                      |
| FREECLKIN    | Input     | Free running version of the core clock                                      |
| FREEDBGTCKEN | Input     | Free running version of the debug clock enable                              |
| ACLKENI      | Input     | Clock enable for Instruction port                                           |
| ACLKENRW     | Input     | Clock enable for data read and data write ports                             |
| ACLKENP      | Input     | Clock enable for peripheral port to enable it to be clocked at a lower rate |
| nPORESETIN   | Input     | Power on reset (resets debug logic)                                         |
| nRESETIN     | Input     | Core reset                                                                  |
| STANDBYWFI   | Output    | Indicates that the processor is in Standby mode                             |

## A.2 Configuration signals

Table A-2 lists the processor configuration signals.

**Table A-2 Configuration signals**

| Name       | Direction | Description                                                |
|------------|-----------|------------------------------------------------------------|
| BIGENDINIT | Input     | When HIGH indicates v5 Bigendian mode                      |
| CFGBIGEND  | Output    | Current state of CP15 Bigend bit                           |
| FIQISNMI   | Input     | When HIGH enables Non-Maskable Fast Interrupts             |
| INITRAM    | Input     | When HIGH indicates Instruction TCM enabled at address 0x0 |
| UBITINIT   | Input     | When HIGH indicates ARMv6 unaligned behavior               |
| VINITHI    | Input     | When HIGH indicates High Vecs mode                         |
| TEINIT     | Input     | When HIGH indicates exceptions taken in Thumb mode         |

A.3 Interrupt signals (including VIC interface signals)

Table A-3 shows the Interrupt signals including signals used on the VIC interface.

Table A-3 Interrupt Signals

| Name           | Direction | Description                                           |
|----------------|-----------|-------------------------------------------------------|
| INTSYNCEN      | Input     | Indicates that the VIC interface is asynchronous      |
| IRQACK         | Output    | Interrupt acknowledge                                 |
| IRQADDR[31:2]  | Input     | Address of IRQ                                        |
| IRQADDRV       | Input     | Indicates <b>IRQADDR</b> is valid                     |
| IRQADDRVSYNCEN | Input     | Indicates that <b>IRQADDRV</b> requires synchronizing |
| nFIQ           | Input     | Fast interrupt request <sup>a</sup>                   |
| nIRQ           | Input     | Interrupt request <sup>a</sup>                        |
| nPMUFIQ        | Output    | Fast interrupt request from System Metrics            |
| nPMUIRQ        | Output    | Interrupt request from System Metrics                 |

a. This signal is level-sensitive and must be held LOW until a suitable interrupt response is received from the processor.

## A.4 AXI interface signals

The AXI interface ports operate using standard AXI signals, described in the following sections:

- *Instruction read port signals*
- *Data port signals* on page A-6
- *Peripheral port signals* on page A-8.

———— **Note** ————

- All the outputs listed in this section have their reset values during Standby.
- Full descriptions of the AXI interface signals are given in the *AMBA® AXI Protocol V1.0 Specification*. This section only summarizes how the AXI interfaces are implemented on this processor.

The AXI signal names have a one or two-letter suffix that indicate the port, as shown in Table A-4.

**Table A-4 Port signal name suffixes**

| Port              | Suffix | Comment    |
|-------------------|--------|------------|
| Instruction fetch | I      | Read-only  |
| Data read/write   | RW     | Read/write |
| Peripheral        | P      | Read/write |

### A.4.1 Instruction read port signals

The instruction read port is a 64-bit wide read-only AXI port. The standard AXI read channel signal names are suffixed with **I**, and the implementation details of the port are:

- **ARID[3:0]** and **RID[3:0]** signals are not implemented
- the read data bus is implemented as **RDATAI[63:0]**
- only a single bit read response input signal is implemented, **RRESPI[1]**
- the **ARSIDEBANDI[4:0]** output is implemented to indicate shared and inner cacheable accesses.

Table A-5 on page A-6 gives more information about the instruction read port AXI implementation. See the *AMBA® AXI Protocol V1.0 Specification* for details of the other signals on this port.

Table A-5 Instruction read port AXI signal implementation

| Name                    | Direction | Type | Description                                                                                                                                                                                              |
|-------------------------|-----------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ARLENI[3:0]</b>      | Output    | Read | Burst length that gives the exact number of transfers:<br>b0000, 1 data transfer<br>b0001, 2 data transfers<br>b0010, 3 data transfers<br>b0011, 4 data transfers, maximum for the instruction read port |
| <b>ARSIZEI[2:0]</b>     | Output    | Read | Burst size, always set to b011, indicating 64-bit transfer                                                                                                                                               |
| <b>ARBURSTI[1:0]</b>    | Output    | Read | Burst type:<br>b01, INCR incrementing burst<br>b10, WRAP Wrapping burst                                                                                                                                  |
| <b>ARLOCKI[1:0]</b>     | Output    | Read | Lock type, always set to b00, indicating normal access                                                                                                                                                   |
| <b>ARSIDEBANDI[4:0]</b> | Output    | -    | Indicates accesses to shared and inner cacheable memory                                                                                                                                                  |

#### A.4.2 Data port signals

The data port is a 64-bit wide read/write AXI port. The standard AXI read channel, write channel, and write response channel signal names are suffixed with **RW**, and the implementation details of the port are:

- **AWID[3:0]**, **WID[3:0]**, **BID[3:0]**, **ARID[3:0]**, and **RID[3:0]** signals are not implemented
- the write data bus is implemented as **WDATARW[63:0]**, and therefore the write strobe signal is implemented as **WSTRBRW[7:0]**
- the read data bus is implemented as **RDATARW[63:0]**
- the **ARSIDEBANDRW[4:0]** output and **AWSIDEBANDRW[4:0]** output signals are implemented to indicate shared and inner cacheable accesses
- the **WRITEBACK** output signal is implemented to indicate cache line evictions.

Table A-6 on page A-7 gives more information about the data port AXI implementation. See the AMBA® AXI Protocol V1.0 Specification for details of the other signals on this port.

**Table A-6 Data port AXI signal implementation**

| <b>Name</b>              | <b>Direction</b> | <b>Type</b> | <b>Description</b>                                                                                                                                                                                                                                 |
|--------------------------|------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AWSIZERW[2:0]</b>     | Output           | Write       | Write burst size:<br>000, 8-bit transfers<br>001, 16-bit transfers<br>010, 32-bit transfers<br>011, 64-bit transfers, maximum for the data port.                                                                                                   |
| <b>AWBURSTRW[1:0]</b>    | Output           | Write       | Write burst type:<br>01, INCR Incrementing burst<br>10, WRAP Wrapping burst.                                                                                                                                                                       |
| <b>AWLOCKRW[1:0]</b>     | Output           | Write       | Write lock type:<br>00, Normal access<br>01, Exclusive access.                                                                                                                                                                                     |
| <b>ARLENRW[3:0]</b>      | Output           | Read        | Burst length that gives the exact number of transfer:<br>b0000, 1 data transfer<br>b0001, 2 data transfers<br>b0010, 3 data transfers<br>b0011, 4 data transfers<br>b0100, 5 data transfers<br>b0101, 6 data transfers<br>b0110, 7 data transfers. |
| <b>ARSizerW[2:0]</b>     | Output           | Read        | Burst size:<br>b000, indicating 8-bit transfer<br>b001, indicating 16-bit transfer<br>b010, indicating 32-bit transfer<br>b011, indicating 64-bit transfer.                                                                                        |
| <b>ARBURSTRW[1:0]</b>    | Output           | Read        | Burst type:<br>b01, INCR, Incrementing burst<br>b10, WRAP, Wrapping burst.                                                                                                                                                                         |
| <b>ARSIDEBANDRW[4:0]</b> | Output           | Read        | Indicates read accesses to shared and inner cacheable memory.                                                                                                                                                                                      |
| <b>AWSIDEBANDRW[4:0]</b> | Output           | Write       | Indicates write accesses to shared and inner cacheable memory.                                                                                                                                                                                     |
| <b>WRITEBACK</b>         | Output           | -           | Indicates that the current transaction is a cache line eviction. This signal has the same timing as the write address channel signals.                                                                                                             |

### A.4.3 Peripheral port signals

The peripheral port is a 32-bit wide read/write AXI port. The standard AXI read channel, write channel, and write response channel signal names are suffixed with **P**, and the implementation details of the port are:

- **AWID[3:0]**, **WID[3:0]**, **BID[3:0]**, **ARID[3:0]**, and **RID[3:0]** signals are not implemented
- the write data bus is implemented as **WDATAP[31:0]**, and therefore the write strobe signal is implemented as **WSTRBP[3:0]**
- the read data bus is implemented as **RDATAP[31:0]**
- the **ARSIDEBANDP[4:0]** output and **AWSIDEBANDP[4:0]** output signals are implemented to indicate shared and inner cacheable accesses. These signals have fixed values.

Table A-7 gives more information about the peripheral port AXI implementation. See the AMBA® AXI Protocol V1.0 Specification for details of the other signals on this port.

**Table A-7 Peripheral port AXI signal implementation**

| Name                 | Direction | Type  | Description                                                                                                                      |
|----------------------|-----------|-------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>AWSIZEP[2:0]</b>  | Output    | Write | Write burst size:<br>b000, 8-bit transfers<br>b001, 16-bit transfers<br>b010, 32-bit transfers, maximum for the peripheral port. |
| <b>AWBURSTP[1:0]</b> | Output    | Write | Write burst type, always set to b01, INCR, Incrementing burst.                                                                   |
| <b>AWLOCKP[1:0]</b>  | Output    | Write | Write lock type, always set to b00, Normal access.                                                                               |
| <b>AWCACHEP[3:0]</b> | Output    | Write | Cache type giving additional information about cacheable characteristics for write accesses. Always set to 0x1.                  |
| <b>ARLENP[3:0]</b>   | Output    | Read  | Burst length that gives the exact number of transfer:<br>b0000, 1 data transfer<br>b0001, 2 data transfers.                      |
| <b>ARSIZEP[2:0]</b>  | Output    | Read  | Burst size:<br>b000, 8-bit transfer<br>b001, 16-bit transfer<br>b010, 32-bit transfer.                                           |

**Table A-7 Peripheral port AXI signal implementation (continued)**

| <b>Name</b>             | <b>Direction</b> | <b>Type</b> | <b>Description</b>                                                                           |
|-------------------------|------------------|-------------|----------------------------------------------------------------------------------------------|
| <b>ARBURSTP[1:0]</b>    | Output           | Read        | Burst type:<br>b01, INCR, Incrementing burst<br>b10, WRAP, Wrapping burst.                   |
| <b>ARLOCKP[1:0]</b>     | Output           | Read        | Lock type:<br>b00, normal access<br>b10, locked transfer.                                    |
| <b>ARCACHEP[3:0]</b>    | Output           | Read        | Cache type giving additional information about cacheable characteristics. Always set to 0x1. |
| <b>ARSIDEBANDP[4:0]</b> | Output           | Read        | Indicates read accesses to shared and inner cacheable memory. Always set to 0x2.             |
| <b>AWSIDEBANDP[4:0]</b> | Output           | Write       | Indicates write accesses to shared and inner cacheable memory. Always set to 0x2.            |

## A.5 Instruction TCM Interface

Table A-8 shows the *Instruction TCM* (ITCM) Interface signals.

**Table A-8 Instruction TCM Interface signals**

| Name                      | Direction | Description                     |
|---------------------------|-----------|---------------------------------|
| <b>CFGITCMSZ[3:0]</b>     | Input     | Size configuration for the ITCM |
| <b>ITCDATAADDR[17:3]</b>  | Output    | Address for ITCM                |
| <b>ITCDATABYTEWR[7:0]</b> | Output    | Byte write enable for the ITCM  |
| <b>ITCDATAEN0</b>         | Output    | Enable for lower word ITCM      |
| <b>ITCDATAEN1</b>         | Output    | Enable for upper word ITCM      |
| <b>ITCDATAERREN</b>       | Output    | Error checking enable for ITCM  |
| <b>ITCDATAERROR[7:0]</b>  | Input     | Error signals for ITCM          |
| <b>ITCDATAIN 63:0]</b>    | Output    | Write data for ITCM             |
| <b>ITCDATAOUT[63:0]</b>   | Input     | Read data for ITCM              |
| <b>ITCDATAPARITY[7:0]</b> | Output    | Parity signals for ITCM         |
| <b>ITCDATASEQ</b>         | Output    | Sequential indicator for ITCM   |
| <b>ITCDATAWRITE</b>       | Output    | Write enable for ITCM           |
| <b>nITCDATARDY</b>        | Input     | Wait signal for ITCM            |

## A.6 Data TCM Interface

Table A-8 on page A-10 shows the *Data TCM* (DTCM) Interface signals.

**Table A-9 Data TCM Interface signals**

| <b>Name</b>               | <b>Direction</b> | <b>Description</b>              |
|---------------------------|------------------|---------------------------------|
| <b>CFGDTCMSZ[3:0]</b>     | Input            | Size configuration for the DTCM |
| <b>DTCDATAADDR[17:3]</b>  | Output           | Address for DTCM                |
| <b>DTCDATABYTEWR[7:0]</b> | Output           | Byte write enable for the DTCM  |
| <b>DTCDATAEN0</b>         | Output           | Enable for lower word DTCM      |
| <b>DTCDATAEN1</b>         | Output           | Enable for upper word DTCM      |
| <b>DTCDATAERREN</b>       | Output           | Error checking enable for DTCM  |
| <b>DTCDATAERROR[7:0]</b>  | Input            | Error signals for DTCM          |
| <b>DTCDATAIN[63:0]</b>    | Output           | Write data for DTCM             |
| <b>DTCDATAOUT[63:0]</b>   | Input            | Read data for DTCM              |
| <b>DTCDATAPARITY[7:0]</b> | Output           | Parity signals for ITCM         |
| <b>DTCDATASEQ</b>         | Output           | Sequential indicator for DTCM   |
| <b>DTCDATAWRITE</b>       | Output           | Write enable for DTCM           |
| <b>nDTCDATARDY</b>        | Input            | Wait signal for DTCM            |

## A.7 Coprocessor interface signals

Table A-10 show the coprocessor interface signals.

**Table A-10 Coprocessor interface signals**

| Name                     | Direction | Description                                                  |
|--------------------------|-----------|--------------------------------------------------------------|
| <b>ACPCANCEL</b>         | Output    | Asserted to indicate the instruction is to be cancelled      |
| <b>ACPCANCEL</b> [3:0]   | Output    | Tag for instruction cancelled by <b>ACPCANCEL</b>            |
| <b>ACPCANCEL</b> V       | Output    | Asserted to indicate <b>ACPCANCEL</b> is valid               |
| <b>ACPENABLE</b> [11:0]  | Output    | Coprocessor enable                                           |
| <b>ACPFINISH</b> V       | Output    | Finish token                                                 |
| <b>ACPFLUSH</b>          | Output    | Instruction flush                                            |
| <b>ACPFLUSH</b> [3:0]    | Output    | Tag for instruction flushed by <b>ACPFLUSH</b>               |
| <b>ACPINSTR</b> [31:0]   | Output    | Instruction bus                                              |
| <b>ACPINSTR</b> [3:0]    | Output    | Tag accompanying the instruction on <b>ACPINSTR</b>          |
| <b>ACPINSTR</b> V        | Output    | Indicates that the instruction on <b>ACPINSTR</b> is valid   |
| <b>ACPLDDATA</b> [63:0]  | Output    | Load data to the coprocessor                                 |
| <b>ACPLDVALID</b>        | Output    | Indicates that the data on <b>ACPLDDATA</b> is valid         |
| <b>ACPSTSTOP</b>         | Output    | Asserted to stop the coprocessor sending the core store data |
| <b>ACPPRIV</b>           | Output    | Indicates that the core is in a privileged mode              |
| <b>CPAACCEPT</b>         | Input     | Bounce signal from coprocessors issue stage                  |
| <b>CPAACCEPT</b> HOLD    | Input     | <b>CPAACCEPT</b> is not valid when this signal is asserted   |
| <b>CPAACCEPT</b> [3:0]   | Input     | Tag for instruction bounced by <b>CPAACCEPT</b>              |
| <b>CPALENGTH</b> [3:0]   | Input     | Transfer length information from coprocessor                 |
| <b>CPALENGTH</b> HOLD    | Input     | <b>CPALENGTH</b> is not valid when this signal is asserted   |
| <b>CPALENGTH</b> [3:0]   | Input     | Instruction tag for <b>CPALENGTH</b>                         |
| <b>CPAPRESENT</b> [11:0] | Input     | Indicates which coprocessors are present                     |

**Table A-10 Coprocessor interface signals (continued)**

| <b>Name</b>            | <b>Direction</b> | <b>Description</b>                            |
|------------------------|------------------|-----------------------------------------------|
| <b>CPASTDATA[63:0]</b> | Input            | Coprocessor store data                        |
| <b>CPASTDATAT[3:0]</b> | Input            | Tag accompanying the data on <b>CPASTDATA</b> |
| <b>CPASTDATAV</b>      | Input            | Indicates that the store data is valid        |

---

**Note**

---

If no coprocessor is connected, the following signals must be driven LOW:

- **CPALENGTHHOLD**
  - **CPAACCEPT**
  - **CPAACCEPTHOLD.**
-

## A.8 Debug interface signals (including JTAG)

Table A-11 lists the debug interface signals including JTAG.

**Table A-11 Debug interface signals**

| <b>Name</b>            | <b>Direction</b> | <b>Description</b>                                     |
|------------------------|------------------|--------------------------------------------------------|
| <b>COMMRX</b>          | Output           | Communications channel receive                         |
| <b>COMMTX</b>          | Output           | Communications channel transmit                        |
| <b>DBGACK</b>          | Output           | Debug Acknowledge                                      |
| <b>DBGEN</b>           | Input            | Debug enable                                           |
| <b>DBGMANID[10:0]</b>  | Input            | Customer field for JTAGID manufacturer field           |
| <b>DBGNOPWRDWN</b>     | Output           | Debugger has requested that system is not powered down |
| <b>DBGnTDOEN</b>       | Output           | Debug <b>nTDOEN</b>                                    |
| <b>DBGnTRST</b>        | Input            | Debug <b>nTRST</b>                                     |
| <b>DBGTDI</b>          | Input            | Debug <b>TDI</b>                                       |
| <b>DBGTDO</b>          | Output           | Debug <b>TDO</b>                                       |
| <b>DBGTMS</b>          | Input            | Debug <b>TMS</b>                                       |
| <b>DBGVERSION[3:0]</b> | Input            | Customer field for JTAGID version field                |
| <b>EDBGRQ</b>          | Input            | External debug request                                 |

## A.9 ETM interface signals

Table A-12 shows the ETM interface signals.

**Table A-12 ETM interface signals**

| Name               | Direction | Description                                                         |
|--------------------|-----------|---------------------------------------------------------------------|
| ETMCPADDRESS[14:0] | Output    | Coprocessor CP14 address.                                           |
| ETMCPCOMMIT        | Output    | Coprocessor CP14 commit.                                            |
| ETMCPENABLE        | Output    | Coprocessor CP14 interface enable.                                  |
| ETMCPRDATA[31:0]   | Input     | Coprocessor CP14 read data.                                         |
| ETMCPWDATA[31:0]   | Output    | Coprocessor CP14 write data.                                        |
| ETMCPWRITE         | Output    | Coprocessor CP14 write control.                                     |
| ETMDA[31:3]        | Output    | ETM data address.                                                   |
| ETMDACTL[17:0]     | Output    | ETM data control (address phase).                                   |
| ETMDD[63:0]        | Output    | ETM data.                                                           |
| ETMDDCTL[3:0]      | Output    | ETM data control (data phase).                                      |
| ETMEXTOUT[1:0]     | Input     | ETM External event to be monitored.                                 |
| ETMIA[31:0]        | Output    | ETM instruction address.                                            |
| ETMICTL[17:0]      | Output    | ETM Instruction control.                                            |
| ETMIARET[31:0]     | Output    | ETM Instruction return address.                                     |
| ETMPADV[2:0]       | Output    | ETM pipeline advance.                                               |
| ETMPWRUP           | Input     | When HIGH indicates that ETM is powered up.                         |
| EVNTBUS[19:0]      | Output    | System metrics event bus.                                           |
| nETMWFIREADY       | Input     | When HIGH indicates ETM can accept Wait For Interrupt.              |
| WFIPENDING         | Output    | Indicates pending Wait For Interrupt. Handshakes with nETMWFIREADY. |

## A.10 Test signals

Table A-13 shows the test signals.

**Table A-13 Test signals**

| Name                   | Direction | Description                                      |
|------------------------|-----------|--------------------------------------------------|
| <b>DTCTESTEN</b>       | Output    | Test enable for Data TDM                         |
| <b>ITCTESEN</b>        | Output    | Test enable for Instruction TDM                  |
| <b>MBISTADDR[14:0]</b> | Input     | <i>Memory Built In Self Test</i> (MBIST) address |
| <b>MBISTCE[16:0]</b>   | Input     | MBIST chip enable                                |
| <b>MBISTDIN[71:0]</b>  | Input     | MBIST data in                                    |
| <b>MBISTDOUT[71:0]</b> | Output    | MBIST data out                                   |
| <b>MBISTWE[7:0]</b>    | Input     | MBIST byte write enables                         |
| <b>MTESTON</b>         | Input     | MBIST test is enabled                            |
| <b>nMBISTDATARDY</b>   | Output    | TCM wait signal when MBIST is run                |
| <b>nVALFIQ</b>         | Output    | Request for a Fast Interrupt                     |
| <b>nVALIRQ</b>         | Output    | Request for an Interrupt                         |
| <b>nVALRESET</b>       | Output    | Request for a reset                              |
| <b>RSTBYPASS</b>       | Input     | Bypass pipelined reset                           |
| <b>SE</b>              | Input     | Scan Enable                                      |
| <b>VALEDBGREQ</b>      | Output    | Request for an external debug request            |

# Glossary

This glossary describes some of the terms and abbreviations used in this manual. Where terms can have several meanings, the meaning presented here is intended.

**Abort** A mechanism that indicates to a core that the value associated with a memory access is invalid. An abort can be caused by the external or internal memory system as a result of attempting to access invalid instruction or data memory. An abort is classified as either a Prefetch or Data Abort, and an internal or External Abort.

*See also* Data Abort, External Abort and Prefetch Abort.

**Abort model** An abort model is the defined behavior of an ARM processor in response to a Data Abort exception. Different abort models behave differently with regard to load and store instructions that specify base register write-back.

**Addressing modes** A mechanism, shared by many different instructions, for generating values used by the instructions. For four of the ARM addressing modes, the values generated are memory addresses (which is the traditional role of an addressing mode). A fifth addressing mode generates values to be used as operands by data-processing instructions.

**Advanced eXtensible Interface (AXI)** This is a bus protocol that supports separate address/control and data phases, unaligned data transfers using byte strobes, burst-based transactions with only start address issued, separate read and write data channels to enable low-cost DMA, ability to issue multiple

outstanding addresses, out-of-order transaction completion, and easy addition of register stages to provide timing closure. The AXI protocol also includes optional extensions to cover signaling for low-power operation.

AXI is targeted at high performance, high clock frequency system designs and includes a number of features that make it very suitable for high speed sub-micron interconnect.

**Advanced High-performance Bus (AHB)**

The AMBA Advanced High-performance Bus system connects embedded processors such as an ARM core to high-performance peripherals, DMA controllers, on-chip memory, and interfaces. It is a high-speed, high-bandwidth bus that supports multi-master bus management to maximize system performance.

*See also* Advanced Microcontroller Bus Architecture.

**Advanced Microcontroller Bus Architecture (AMBA)**

AMBA is the ARM open standard for multi-master on-chip buses, capable of running with multiple masters and slaves. It is an on-chip bus specification that details a strategy for the interconnection and management of functional blocks that make up a System-on-Chip (SoC). It aids in the development of embedded processors with one or more CPUs or signal processors and multiple peripherals. AMBA complements a reusable design methodology by defining a common backbone for SoC modules. AHB, APB, and AXI conform to this standard.

**Advanced Peripheral Bus (APB)**

The AMBA Advanced Peripheral Bus is a simpler bus protocol than AHB. It is designed for use with ancillary or general-purpose peripherals such as timers, interrupt controllers, UARTs, and I/O ports. Connection to the main system bus is through a system-to-peripheral bus bridge that helps to reduce system power consumption.

*See also* Advanced High-performance Bus.

**AHB**

*See* Advanced High-performance Bus.

**Aligned**

A data item stored at an address that is divisible by the number of bytes that defines the data size is said to be aligned. Aligned words and halfwords have addresses that are divisible by four and two respectively. The terms word-aligned and halfword-aligned therefore stipulate addresses that are divisible by four and two respectively.

**AMBA**

*See* Advanced Microcontroller Bus Architecture.

**APB**

*See* Advanced Peripheral Bus.

**Application Specific Integrated Circuit (ASIC)**

An integrated circuit that has been designed to perform a specific application function. It can be custom-built or mass-produced.

|                                 |                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Architecture</b>             | The organization of hardware and/or software that characterizes a processor and its attached components, and enables devices with similar characteristics to be grouped together when describing their behavior, for example, Harvard architecture, instruction set architecture, ARMv6 architecture.                                                       |
| <b>Arithmetic instruction</b>   | Any VFPv2 <i>Coprocessor Data Processing</i> (CDP) instruction except FCPY, FABS, and FNEG.<br><br><i>See also</i> CDP instruction.                                                                                                                                                                                                                         |
| <b>ARM instruction</b>          | A word that specifies an operation for an ARM processor to perform. ARM instructions must be word-aligned.                                                                                                                                                                                                                                                  |
| <b>ARM state</b>                | A processor that is executing ARM (32-bit) word-aligned instructions is operating in ARM state.                                                                                                                                                                                                                                                             |
| <b>ASIC</b>                     | <i>See</i> Application Specific Integrated Circuit.                                                                                                                                                                                                                                                                                                         |
| <b>AXI</b>                      | <i>See</i> Advanced eXtensible Interface.                                                                                                                                                                                                                                                                                                                   |
| <b>Banked registers</b>         | Those physical registers whose use is defined by the current processor mode. The banked registers are r8 to r14.                                                                                                                                                                                                                                            |
| <b>Base register</b>            | A register specified by a load/store instruction that is used to hold the base value for the instruction's address calculation. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the virtual address that is sent to memory.                                              |
| <b>Base register write-back</b> | Updating the contents of the base register used in an instruction target address calculation so that the modified address is changed to the next higher or lower sequential address in memory. This means that it is not necessary to fetch the target address for successive instruction transfers and enables faster burst accesses to sequential memory. |
| <b>Beat</b>                     | Alternative word for an individual transfer within a burst. For example, an INCR4 burst comprises four beats.<br><br><i>See also</i> Burst.                                                                                                                                                                                                                 |
| <b>BE-8</b>                     | Big-endian view of memory in a byte-invariant system.<br><br><i>See also</i> BE-32, LE, Byte-invariant and Word-invariant.                                                                                                                                                                                                                                  |
| <b>BE-32</b>                    | Big-endian view of memory in a word-invariant system.<br><br><i>See also</i> BE-8, LE, Byte-invariant and Word-invariant.                                                                                                                                                                                                                                   |

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Big-endian</b>          | Byte ordering scheme in which bytes of decreasing significance in a data word are stored at increasing addresses in memory.<br><br><i>See also</i> Little-endian and Endianness.                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Big-endian memory</b>   | Memory in which:- a byte or halfword at a word-aligned address is the most significant byte or halfword within the word at that address - a byte at a halfword-aligned address is the most significant byte within the halfword at that address.<br><br><i>See also</i> Little-endian memory.                                                                                                                                                                                                                                                      |
| <b>Block address</b>       | An address that comprises a tag, an index, and a word field. The tag bits identify the way that contains the matching cache entry for a cache hit. The index bits identify the set being addressed. The word field contains the word address that can be used to identify specific words, halfwords, or bytes within the cache entry.<br><br><i>See also</i> Cache terminology diagram on the last page of this glossary.                                                                                                                          |
| <b>Bounce</b>              | The VFP coprocessor is said to bounce an instruction when it signals the rejection of a valid VFP instruction to the ARM processor. This action initiates Undefined instruction processing by the ARM processor. The VFP support code is called to complete the instruction that was found to be exceptional or unsupported by the VFP coprocessor.<br><br><i>See also</i> Trigger instruction, Potentially exceptional instruction, and Exceptional state.                                                                                        |
| <b>Boundary scan chain</b> | A boundary scan chain is made up of serially-connected devices that implement boundary scan technology using a standard JTAG TAP interface. Each device contains at least one TAP controller containing shift registers that form the chain connected between <b>TDI</b> and <b>TDO</b> , through which test data is shifted. Processors can contain several shift registers to enable you to access selected parts of the device.                                                                                                                 |
| <b>Branch folding</b>      | Branch folding is a technique where, on the prediction of most branches, the branch instruction is completely removed from the instruction stream presented to the execution pipeline. Branch folding can significantly improve the performance of branches, taking the CPI for branches below one.                                                                                                                                                                                                                                                |
| <b>Branch phantom</b>      | The condition codes of a predicted taken branch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Branch prediction</b>   | The process of predicting if conditional branches are to be taken or not in pipelined processors. Successfully predicting if branches are to be taken enables the processor to prefetch the instructions following a branch before the condition is fully resolved. Branch prediction can be done in software or by using custom hardware. Branch prediction techniques are categorized as static, in which the prediction decision is decided before run time, and dynamic, in which the prediction decision can change during program execution. |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Breakpoint</b>       | <p>A breakpoint is a mechanism provided by debuggers to identify an instruction at which program execution is to be halted. Breakpoints are inserted by the programmer to enable inspection of register contents, memory locations, variable values at fixed points in the program execution to test that the program is operating correctly. Breakpoints are removed after the program is successfully tested.</p> <p><i>See also</i> Watchpoint.</p>                                                                                                                                                                                         |
| <b>Burst</b>            | <p>A group of transfers to consecutive addresses. Because the addresses are consecutive, there is no requirement to supply an address for any of the transfers after the first one. This increases the speed at which the group of transfers can occur. Bursts over AHB or AXI buses are controlled using the <b>xBURST</b> signals to specify if transfers are single, four-beat, eight-beat, or 16-beat bursts, and to specify how the addresses are incremented.</p> <p><i>See also</i> Beat.</p>                                                                                                                                           |
| <b>Byte</b>             | An 8-bit data item.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Byte invariant</b>   | <p>In a byte-invariant system, the address of each byte of memory remains unchanged when switching between little-endian and big-endian operation. When a data item larger than a byte is loaded from or stored to memory, the bytes making up that data item are arranged into the correct order depending on the endianness of the memory access. The ARM architecture supports byte-invariant systems in ARMv6 and later versions. When byte-invariant support is selected, unaligned halfword and word memory accesses are also supported. Multi-word accesses are expected to be word-aligned.</p> <p><i>See also</i> Word-invariant.</p> |
| <b>Byte lane strobe</b> | An AHB signal, <b>HBSTRB</b> , that is used for unaligned or mixed-endian data accesses to determine which byte lanes are active in a transfer. One bit of <b>HBSTRB</b> corresponds to eight bits of the data bus.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Byte swizzling</b>   | The reverse ordering of bytes in a word.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Cache</b>            | <p>A block of on-chip or off-chip fast access memory locations, situated between the processor and main memory, used for storing and retrieving copies of often used instructions and/or data. This is done to greatly increase the average speed of memory accesses and so improve processor performance.</p> <p><i>See also</i> Cache terminology diagram on the last page of this glossary.</p>                                                                                                                                                                                                                                             |
| <b>Cache contention</b> | When the number of frequently-used memory cache lines that use a particular cache set exceeds the set-associativity of the cache. In this case, main memory activity increases and performance decreases.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Cache hit</b>        | A memory access that can be processed at high speed because the instruction or data that it addresses is already held in the cache.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Cache line</b>              | <p>The basic unit of storage in a cache. It is always a power of two words in size (usually four or eight words), and is required to be aligned to a suitable memory boundary.</p> <p><i>See also</i> Cache terminology diagram on the last page of this glossary.</p>                                                                                                                                                                                                |
| <b>Cache line index</b>        | <p>The number associated with each cache line in a cache set. Within each cache set, the cache lines are numbered from 0 to (set associativity) -1.</p> <p><i>See also</i> Cache terminology diagram on the last page of this glossary.</p>                                                                                                                                                                                                                           |
| <b>Cache lockdown</b>          | <p>To fix a line in cache memory so that it cannot be overwritten. Cache lockdown enables critical instructions and/or data to be loaded into the cache so that the cache lines containing them are not subsequently reallocated. This ensures that all subsequent accesses to the instructions/data concerned are cache hits, and therefore complete as quickly as possible.</p> <p><i>See also</i> Cache terminology diagram on the last page of this glossary.</p> |
| <b>Cache miss</b>              | <p>A memory access that cannot be processed at high speed because the instruction/data it addresses is not in the cache and a main memory access is required.</p>                                                                                                                                                                                                                                                                                                     |
| <b>Cache set</b>               | <p>A cache set is a group of cache lines (or blocks). A set contains all the ways that can be addressed with the same index. The number of cache sets is always a power of two. All sets are accessed in parallel during a cache look-up.</p> <p><i>See also</i> Cache terminology diagram on the last page of this glossary.</p>                                                                                                                                     |
| <b>Cache set associativity</b> | <p>The maximum number of cache lines that can be held in a cache set.</p> <p><i>See also</i> Set-associative cache and Cache terminology diagram on the last page of this glossary.</p>                                                                                                                                                                                                                                                                               |
| <b>Cache way</b>               | <p>A group of cache lines (or blocks). It is 2 to the power of the number of index bits in size.</p> <p><i>See also</i> Cache terminology diagram on the last page of this glossary.</p>                                                                                                                                                                                                                                                                              |
| <b>Cast out</b>                | <p><i>See</i> Victim.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>CDP instruction</b>         | <p>Coprocessor data processing instruction. For the VFP11 coprocessor, CDP instructions are arithmetic instructions and FCPY, FABS, and FNEG.</p> <p><i>See also</i> Arithmetic instruction.</p>                                                                                                                                                                                                                                                                      |
| <b>Clean</b>                   | <p>A cache line that has not been modified while it is in the cache is said to be clean. To clean a cache is to write dirty cache entries into main memory. If a cache line is clean, it is not written on a cache miss because the next level of memory contains the same data as the cache.</p> <p><i>See also</i> Dirty.</p>                                                                                                                                       |

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Clock gating</b>                 | Gating a clock signal for a macrocell with a control signal (such as <b>PWRDOWN</b> ) and using the modified clock that results to control the operating state of the macrocell.                                                                                                                                                                                                                                                                                                               |
| <b>Clocks Per Instruction (CPI)</b> | <i>See</i> Cycles Per Instruction (CPI).                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Coherency</b>                    | <i>See</i> Memory coherency.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Cold reset</b>                   | Also known as power-on reset. Starting the processor by turning power on. Turning power off and then back on again clears main memory and many internal settings. Some program failures can lock up the processor and require a cold reset to enable the system to be used again. In other cases, only a warm reset is required.<br><br><i>See also</i> Warm reset.                                                                                                                            |
| <b>Communications channel</b>       | The hardware used for communicating between the software running on the processor, and an external host, using the debug interface. When this communication is for debug purposes, it is called the Debug Communications Channel. In an ARMv6 compliant core, the communications channel includes the Data Transfer Register, some bits of the Data Status and Control Register, and the external debug interface controller, such as the DBGTap controller in the case of the JTAG interface. |
| <b>Condition field</b>              | A 4-bit field in an instruction that is used to specify a condition under which the instruction can execute.                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Conditional execution</b>        | If the condition code flags indicate that the corresponding condition is true when the instruction starts executing, it executes normally. Otherwise, the instruction does nothing.                                                                                                                                                                                                                                                                                                            |
| <b>Context</b>                      | The environment that each process operates in for a multitasking operating system. In ARM processors, this is limited to mean the physical address range that it can access in memory and the associated memory access permissions.                                                                                                                                                                                                                                                            |
| <b>Control bits</b>                 | The bottom eight bits of a Program Status Register (PSR). The control bits change when an exception arises and can be altered by software only when the processor is in a privileged mode.                                                                                                                                                                                                                                                                                                     |
| <b>Coprocessor</b>                  | A processor that supplements the main processor. It carries out additional functions that the main processor cannot perform. Usually used for floating-point math calculations, signal processing, or memory management.                                                                                                                                                                                                                                                                       |
| <b>Copy back</b>                    | <i>See</i> Write-back.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Core</b>                         | A core is that part of a processor that contains the ALU, the datapath, the general-purpose registers, the Program Counter, and the instruction decode and control circuitry.                                                                                                                                                                                                                                                                                                                  |

|                                               |                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Core module</b>                            | In the context of an ARM Integrator, a core module is an add-on development board that contains an ARM processor and local memory. Core modules can run standalone, or can be stacked onto Integrator motherboards.                                                                                                                         |
| <b>Core reset</b>                             | <i>See</i> Warm reset.                                                                                                                                                                                                                                                                                                                      |
| <b>CPI</b>                                    | <i>See</i> Cycles per instruction.                                                                                                                                                                                                                                                                                                          |
| <b>CPSR</b>                                   | <i>See</i> Current Program Status Register.                                                                                                                                                                                                                                                                                                 |
| <b>Current Program Status Register (CPSR)</b> | The register that holds the current operating processor status.                                                                                                                                                                                                                                                                             |
| <b>Cycles Per instruction (CPI)</b>           | Cycles per instruction (or clocks per instruction) is a measure of the number of computer instructions that can be performed in one clock cycle. This figure of merit can be used to compare the performance of different CPUs that implement the same instruction set against each other. The lower the value, the better the performance. |
| <b>CoreSight</b>                              | The infrastructure for monitoring, tracing, and debugging a complete system on chip.                                                                                                                                                                                                                                                        |
| <b>Data Abort</b>                             | An indication from a memory system to the core of an attempt to access an illegal data memory location. An exception must be taken if the processor attempts to use the data that caused the abort.<br><br><i>See also</i> Abort, External Abort, and Prefetch Abort.                                                                       |
| <b>Data cache</b>                             | A block of on-chip fast access memory locations, situated between the processor and main memory, used for storing and retrieving copies of often used data. This is done to greatly increase the average speed of memory accesses and so improve processor performance.                                                                     |
| <b>DBGTAP</b>                                 | <i>See</i> Debug Test Access Port.                                                                                                                                                                                                                                                                                                          |
| <b>Debugger</b>                               | A debugging system that includes a program, used to detect, locate, and correct software faults, together with custom hardware that supports software debugging.                                                                                                                                                                            |
| <b>Debug Test Access Port (DBGTAP)</b>        | The collection of four mandatory and one optional terminals that form the input/output and control interface to a JTAG boundary-scan architecture. The mandatory terminals are <b>DBGTDI</b> , <b>DBGTDO</b> , <b>DBGTMS</b> , and <b>TCK</b> . The optional terminal is <b>TRST</b> .                                                      |
| <b>Default NaN mode</b>                       | A mode in which all operations that result in a NaN return the default NaN, regardless of the cause of the NaN result. This mode is compliant with the IEEE 754 standard but implies that all information contained in any input NaNs to an operation is lost.                                                                              |
| <b>Denormalized value</b>                     | <i>See</i> Subnormal value.                                                                                                                                                                                                                                                                                                                 |

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Dirty</b>                          | <p>A cache line in a write-back cache that has been modified while it is in the cache is said to be dirty. A cache line is marked as dirty by setting the dirty bit. If a cache line is dirty, it must be written to memory on a cache miss because the next level of memory contains data that has not been updated. The process of writing dirty data to main memory is called cache cleaning.</p> <p><i>See also</i> Clean.</p> |
| <b>Disabled exception</b>             | <p>An exception is disabled when its exception enable bit in the FPCSR is not set. For these exceptions, the IEEE 754 standard defines the result to be returned. An operation that generates an exception condition can bounce to the support code to produce the result defined by the IEEE 754 standard. The exception is not reported to the user trap handler.</p>                                                            |
| <b>DNM</b>                            | <i>See</i> Do Not Modify.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Do Not Modify (DNM)</b>            | <p>In Do Not Modify fields, the value must not be altered by software. DNM fields read as Unpredictable values, and must only be written with the same value read from the same field on the same processor. DNM fields are sometimes followed by RAZ or RAO in parentheses to show which way the bits should read for future compatibility, but programmers must not rely on this behavior.</p>                                   |
| <b>Double-precision value</b>         | <p>Consists of two 32-bit words that must appear consecutively in memory and must both be word-aligned, and that is interpreted as a basic double-precision floating-point number according to the IEEE 754-1985 standard.</p>                                                                                                                                                                                                     |
| <b>Doubleword</b>                     | <p>A 64-bit data item. The contents are taken as being an unsigned integer unless otherwise stated.</p>                                                                                                                                                                                                                                                                                                                            |
| <b>EmbeddedICE logic</b>              | <p>An on-chip logic block that provides TAP-based debug support for ARM processor cores. It is accessed through the TAP controller on the ARM core using the JTAG interface.</p>                                                                                                                                                                                                                                                   |
| <b>Embedded Trace Macrocell (ETM)</b> | <p>A hardware macrocell that, when connected to a processor core, outputs instruction and data trace information on a trace port. The ETM provides processor driven trace through a trace port compliant to the ATB protocol.</p>                                                                                                                                                                                                  |
| <b>EmbeddedICE-RT</b>                 | <p>The JTAG-based hardware provided by debuggable ARM processors to aid debugging in real-time.</p>                                                                                                                                                                                                                                                                                                                                |
| <b>Enabled exception</b>              | <p>An exception is enabled when its exception enable bit in the FPCSR is set. When an enabled exception occurs, a trap to the user handler is taken. An operation that generates an exception condition might bounce to the support code to produce the result defined by the IEEE 754 standard. The exception is then reported to the user trap handler.</p>                                                                      |

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Endianness</b>                | <p>Byte ordering. The scheme that determines the order in which successive bytes of a data word are stored in memory. An aspect of the system's memory mapping.</p> <p><i>See also</i> Little-endian and Big-endian</p>                                                                                                                                                                                                                                                                                                                                  |

| <b>Event</b>                     | <p>1 (Simple) An observable condition that can be used by an ETM to control aspects of a trace.</p> <p>2 (Complex) A boolean combination of simple events that is used by an ETM to control aspects of a trace.</p>                                                                                                                                                                                                                                                                                                                                      |
| <b>Exception</b>                 | <p>A fault or error event that is considered serious enough to require that program execution is interrupted. Examples include attempting to perform an invalid memory access, external interrupts, and undefined instructions. When an exception occurs, normal program flow is interrupted and execution is resumed at the corresponding exception vector. This contains the first instruction of the interrupt handler to deal with the exception.</p>                                                                                                |
| <b>Exceptional state</b>         | <p>When a potentially exceptional instruction is issued, the VFP11 coprocessor sets the EX bit, FPEXC[31], and loads a copy of the potentially exceptional instruction in the FPINST register. If the instruction is a short vector operation, the register fields in FPINST are altered to point to the potentially exceptional iteration. When in the exceptional state, the issue of a trigger instruction to the VFP11 coprocessor causes a bounce.</p> <p><i>See also</i> Bounce, Potentially exceptional instruction, and Trigger instruction.</p> |
| <b>Exception service routine</b> | <p><i>See</i> Interrupt handler.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Exception vector</b>          | <p><i>See</i> Interrupt vector.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Exponent</b>                  | <p>The component of a floating-point number that normally signifies the integer power to which two is raised in determining the value of the represented number.</p>                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>External Abort</b>            | <p>An indication from an external memory system to a core that the value associated with a memory access is invalid. An external abort is caused by the external memory system as a result of attempting to access invalid memory.</p> <p><i>See also</i> <i>See also</i> Abort, Data Abort and Prefetch Abort</p>                                                                                                                                                                                                                                       |
| <b>Flush-to-zero mode</b>        | <p>In this mode, the VFP11 coprocessor treats the following values as positive zeros:</p> <ul style="list-style-type: none"><li>• arithmetic operation inputs that are in the subnormal range for the input precision</li><li>• arithmetic operation results, other than computed zero results, that are in the subnormal range for the input precision before rounding.</li></ul>                                                                                                                                                                       |

The VFP11 coprocessor does not interpret these values as subnormal values or convert them to subnormal values.

The subnormal range for the input precision is  $-2^{E_{min}} < x < 0$  or  $0 < x < 2^{E_{min}}$ .

|                               |                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Fraction</b>               | The floating-point field that lies to the right of the implied binary point.                                                                                                                                                                                                                                                                      |
| <b>Halfword</b>               | A 16-bit data item.                                                                                                                                                                                                                                                                                                                               |
| <b>Halting debug-mode</b>     | One of two mutually exclusive debug modes. In Halting debug-mode all processor execution halts when a breakpoint or watchpoint is encountered. All processor state, coprocessor state, memory and input/output locations can be examined and altered by the JTAG interface.<br><br><i>See also</i> Monitor debug-mode.                            |
| <b>High vectors</b>           | Alternative locations for exception vectors. The high vector address range is near the top of the address space, rather than at the bottom.                                                                                                                                                                                                       |
| <b>Hit-Under-Miss (HUM)</b>   | A buffer that enables program execution to continue, even though there has been a data miss in the cache.                                                                                                                                                                                                                                         |
| <b>Host</b>                   | A computer that provides data and other services to another computer. Especially, a computer providing debugging services to a target being debugged.                                                                                                                                                                                             |
| <b>HUM</b>                    | <i>See</i> Hit-Under-Miss.                                                                                                                                                                                                                                                                                                                        |
| <b>IEEE 754 standard</b>      | <i>IEEE Standard for Binary Floating-Point Arithmetic, ANSI/IEEE Std 754-1985.</i> The standard that defines data types, correct operation, exception types and handling, and error bounds for floating-point systems. Most processors are built in compliance with the standard either in hardware or in a combination of hardware and software. |
| <b>IGN</b>                    | <i>See</i> Ignore.                                                                                                                                                                                                                                                                                                                                |
| <b>Ignore (IGN)</b>           | Must ignore memory writes.                                                                                                                                                                                                                                                                                                                        |
| <b>Illegal instruction</b>    | An instruction that is architecturally Undefined.                                                                                                                                                                                                                                                                                                 |
| <b>IMB</b>                    | <i>See</i> Instruction Memory Barrier.                                                                                                                                                                                                                                                                                                            |
| <b>Implementation-defined</b> | Means that the behavior is not architecturally defined, but should be defined and documented by individual implementations.                                                                                                                                                                                                                       |

## Implementation-specific

Means that the behavior is not architecturally defined, and does not have to be documented by individual implementations. Used when there are a number of implementation options available and the option chosen does not affect software compatibility.

**Infinity** In the IEEE 754 standard format to represent infinity, the exponent is the maximum for the precision and the fraction is all zeros.

**Input exception** An exception condition in which one or more of the operands for a given operation are not supported by the hardware. The operation bounces to support code for processing.

**Instruction cache** A block of on-chip fast access memory locations, situated between the processor and main memory, used for storing and retrieving copies of often used instructions. This is done to greatly increase the average speed of memory accesses and so improve processor performance.

## Instruction Memory Barrier (IMB)

An operation to ensure that the prefetch buffer is flushed of all out-of-date instructions.

**Intermediate result** An internal format used to store the result of a calculation before rounding. This format can have a larger exponent field and fraction field than the destination format.

**Interrupt handler** A program to which control of the processor is passed when an interrupt occurs.

**Interrupt vector** One of a number of fixed addresses in low memory, or in high memory if high vectors are configured, that contains the first instruction of the corresponding interrupt handler.

**Invalidate** To mark a cache line as being not valid by clearing the valid bit. This must be done whenever the line does not contain a valid cache entry. For example, after a cache flush all lines are invalid.

## Joint Test Action Group (JTAG)

The name of the organization that developed standard IEEE 1149.1. This standard defines a boundary-scan architecture used for in-circuit testing of integrated circuit devices. It is commonly known by the initials JTAG.

**JTAG** *See* Joint Test Action Group.

**LE** Little endian view of memory in both byte-invariant and word-invariant systems. *See* also Byte-invariant, Word-invariant.

**Line** *See* Cache line.

**Little-endian** Byte ordering scheme in which bytes of increasing significance in a data word are stored at increasing addresses in memory.

*See also* Big-endian and Endianness.

**Little-endian memory**

Memory in which: - a byte or halfword at a word-aligned address is the least significant byte or halfword within the word at that address - a byte at a halfword-aligned address is the least significant byte within the halfword at that address.

*See also* Big-endian memory.

**Load/store architecture**

A processor architecture where data-processing operations only operate on register contents, not directly on memory contents.

**Load Store Unit (LSU)**

The part of a processor that handles load and store transfers.

**LSU**

*See* Load Store Unit.

**Macrocell**

A complex logic block with a defined interface and behavior. A typical VLSI system comprises several macrocells (such as a processor, an ETM, and a memory block) plus application-specific logic.

**Memory coherency**

A memory is coherent if the value read by a data read or instruction fetch is the value that was most recently written to that location. Memory coherency is made difficult when there are multiple possible physical locations that are involved, such as a system that has main memory, a write buffer and a cache.

**Memory Protection Unit (MPU)**

Hardware that controls access permissions to blocks of memory. Unlike an MMU, an MPU does not translate virtual addresses to physical addresses.

**Microprocessor**

*See* Processor.

**Miss**

*See* Cache miss.

**Monitor debug-mode**

One of two mutually exclusive debug modes. In Monitor debug-mode the processor enables a software abort handler provided by the debug monitor or operating system debug task. When a breakpoint or watchpoint is encountered, this enables vital system interrupts to continue to be serviced while normal program execution is suspended.

*See also* Halting debug-mode.

**MPU**

*See* Memory Protection Unit.

**NaN**

Not a number. A symbolic entity encoded in a floating-point format that has the maximum exponent field and a nonzero fraction. An SNaN causes an invalid operand exception if used as an operand and a most significant fraction bit of zero. A QNaN propagates through almost every arithmetic operation without signaling exceptions and has a most significant fraction bit of one.

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Penalty</b>                             | The number of cycles in which no useful Execute stage pipeline activity can occur because the instruction flow is different from that assumed or predicted.                                                                                                                                                                                                                                                                                                              |
| <b>Potentially exceptional instruction</b> | <p>An instruction that is determined, based on the exponents of the operands and the sign bits, to have the potential to produce an overflow, underflow, or invalid condition. After this determination is made, the instruction that has the potential to cause an exception causes the VFP11 coprocessor to enter the exceptional state and bounce the next trigger instruction issued.</p> <p><i>See also</i> Bounce, Trigger instruction, and Exceptional state.</p> |
| <b>Power-on reset</b>                      | <i>See</i> Cold reset.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Prefetching</b>                         | In pipelined processors, the process of fetching instructions from memory to fill up the pipeline before the preceding instructions have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.                                                                                                                                                                                                                           |
| <b>Prefetch Abort</b>                      | <p>An indication from a memory system to the core that an instruction has been fetched from an illegal memory location. An exception must be taken if the processor attempts to execute the instruction. A Prefetch Abort can be caused by the external or internal memory system as a result of attempting to access invalid instruction memory.</p> <p><i>See also</i> Data Abort, External Abort and Abort.</p>                                                       |
| <b>Processor</b>                           | A contraction of microprocessor. A processor includes the CPU or core, plus additional components such as memory, and interfaces. These are combined as a single macrocell, that can be fabricated on an integrated circuit.                                                                                                                                                                                                                                             |
| <b>Read</b>                                | Reads are defined as memory operations that have the semantics of a load. That is, the ARM instructions LDM, LDRD, LDC, LDR, LDRT, LDRSH, LDRH, LDRSB, LDRB, LDRBT, LDREX, RFE, STREX, SWP, and SWPB, and the Thumb instructions LDM, LDR, LDRSH, LDRH, LDRSB, LDRB, and POP.                                                                                                                                                                                            |
| <b>RealView ICE</b>                        | RealView ICE is a system for debugging embedded processor cores that uses a JTAG interface.                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Region</b>                              | A partition of instruction or data memory space.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Reserved</b>                            | A field in a control register or instruction format is reserved if the field is to be defined by the implementation, or produces Unpredictable results if the contents of the field are not zero. These fields are reserved for use in future extensions of the architecture or are implementation-specific. All reserved bits not used by the implementation must be written as 0 and are to be read as 0.                                                              |

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Rounding mode</b>                        | <p>The IEEE 754 standard requires all calculations to be performed as if to an infinite precision. For example, a multiply of two single-precision values must accurately calculate the significand to twice the number of bits of the significand. To represent this value in the destination precision, rounding of the significand is often required. The IEEE 754 standard specifies four rounding modes.</p> <p>In round-to-nearest mode, the result is rounded at the halfway point, with the tie case rounding up if it would clear the least significant bit of the significand, making it even. Round-towards-zero mode chops any bits to the right of the significand, always rounding down, and is used by the C, C++, and Java languages in integer conversions. Round-towards-plus-infinity mode and round-towards-minus-infinity mode are used in interval arithmetic.</p> |
| <b>RunFast mode</b>                         | <p>In RunFast mode, hardware handles exceptional conditions and special operands. RunFast mode is enabled by enabling default NaN and flush-to-zero modes and disabling all exceptions. In RunFast mode, the VFP11 coprocessor does not bounce to the support code for any legal operation or any operand, but supplies a result to the destination. For all inexact and overflow results and all invalid operations that result from operations not involving NaNs, the result is as specified by the IEEE 754 standard. For operations involving NaNs, the result is the default NaN.</p>                                                                                                                                                                                                                                                                                              |
| <b>Saved Program Status Register (SPSR)</b> | <p>The register that holds the CPSR of the task immediately before the exception occurred that caused the switch to the current mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Set-associative cache</b>                | <p>In a set-associative cache, lines can only be placed in the cache in locations that correspond to the modulo division of the memory address by the number of sets. If there are <math>n</math> ways in a cache, the cache is termed <math>n</math>-way set-associative. The set-associativity can be any number greater than or equal to 1 and is not restricted to being a power of two.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Short vector operation</b>               | An operation involving more than one destination register and perhaps more than one source register in the generation of the result for each destination.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Should Be One (SBO)**

Should be written as 1 (or all 1s for bitfields) by software. Writing a 0 produces Unpredictable results.

**Should Be Zero (SBZ)**

Should be written as 0 (or all 0s for bitfields) by software. Writing a 1 produces Unpredictable results.

**Should Be Zero or Preserved (SBZP)**

Should be written as 0 (or all 0s for bitfields) by software, or preserved by writing the same value back that has been previously read from the same field on the same processor.

**Significand**

The component of a binary floating-point number that consists of an explicit or implicit leading bit to the left of the implied binary point and a fraction field to the right.

**SPSR**

*See* Saved Program Status Register

**Stride**

The stride field, FPSCR[21:20], specifies the increment applied to register addresses in short vector operations. A stride of 00, specifying an increment of +1, causes a short vector operation to increment each vector register by +1 for each iteration, while a stride of 11 specifies an increment of +2.

**Subnormal value**

A value in the range ( $-2^{E_{min}} < x < 2^{E_{min}}$ ), except for 0. In the IEEE 754 standard format for single-precision and double-precision operands, a subnormal value has a zero exponent and a nonzero fraction field. The IEEE 754 standard requires that the generation and manipulation of subnormal operands be performed with the same precision as normal operands.

**Support code**

Software that must be used to complement the hardware to provide compatibility with the IEEE 754 standard. The support code has a library of routines that performs supported functions, such as divide with unsupported inputs or inputs that might generate an exception as well as operations beyond the scope of the hardware. The support code has a set of exception handlers to process exceptional conditions in compliance with the IEEE 754 standard.

**Synchronization primitive**

The memory synchronization primitive instructions are those instructions that are used to ensure memory synchronization. That is, the LDREX, STREX, SWP, and SWPB instructions.

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Tag</b>                          | <p>The upper portion of a block address used to identify a cache line within a cache. The block address from the CPU is compared with each tag in a set in parallel to determine if the corresponding line is in the cache. If it is, it is said to be a cache hit and the line can be fetched from cache. If the block address does not correspond to any of the tags, it is said to be a cache miss and the line must be fetched from the next level of memory.</p> <p><i>See also</i> Cache terminology diagram on the last page of this glossary.</p>                                                                               |
| <b>TAP</b>                          | <i>See</i> Debug test access port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Thumb state</b>                  | A processor that is executing Thumb (16-bit) halfword aligned instructions is operating in Thumb state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Tightly coupled memory (TCM)</b> | An area of low latency memory that provides predictable instruction execution or data load timing in cases where deterministic performance is required. TCMs are suited to holding: - critical routines (such as for interrupt handling) - scratchpad data - data types whose locality is not suited to caching - critical data structures (such as interrupt stacks).                                                                                                                                                                                                                                                                  |
| <b>Tiny</b>                         | A nonzero result or value that is between the positive and negative minimum normal values for the destination precision.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Trace port</b>                   | A port on a device, such as a processor or ASIC, used to output trace information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Trap</b>                         | A exceptional condition that has the respective exception enable bit set in the FPSCR register. The user trap handler is executed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Trigger instruction</b>          | <p>The instruction that causes a bounce at the time it is issued. A potentially exceptional instruction causes the VFP11 coprocessor to enter the exceptional state. A subsequent instruction, unless it is an FMXR or FMRX instruction accessing the FPEXC, FPINST, or FPSID register, causes a bounce, beginning exception processing. The trigger instruction is not necessarily exceptional, and no processing of it is performed. It is retried at the return from exception processing of the potentially exceptional instruction.</p> <p><i>See also</i> Bounce, Potentially exceptional instruction, and Exceptional state.</p> |
| <b>Unaligned</b>                    | A data item stored at an address that is not divisible by the number of bytes that defines the data size is said to be unaligned. For example, a word stored at an address that is not divisible by four.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Undefined</b>                    | Indicates an instruction that generates an Undefined instruction trap. See the <i>ARM Architecture Reference Manual</i> for more information on ARM exceptions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>UNP</b>                          | <i>See</i> Unpredictable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Unpredictable</b>                | <p>The result of an instruction or control register field value that cannot be relied upon. Unpredictable instructions or results must not represent security holes, or halt or hang the processor, or any parts of the system.</p>                                                                                                                                                                                                                                                                                                                                                                                                     |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Unsupported values</b> | Specific data values that are not processed by the hardware but bounced to the support code for completion. These data can include infinities, NaNs, subnormal values, and zeros. An implementation is free to select which of these values is supported in hardware fully or partially, or requires assistance from support code to complete the operation. Any exception resulting from processing unsupported data is trapped to user code if the corresponding exception enable bit for the exception is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Vector operation</b>   | A VFP coprocessor operation involving more than one destination register, perhaps involving different source registers in the generation of the result for each destination.<br><br><i>See also</i> Scalar operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Victim</b>             | A cache line, selected to be discarded to make room for a replacement cache line that is required as a result of a cache miss. The way in which the victim is selected for eviction is processor-specific. A victim is also known as a cast out.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Warm reset</b>         | Also known as a core reset. Initializes the majority of the processor excluding the debug controller and debug logic. This type of reset is useful if you are using the debugging features of a processor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Watchpoint</b>         | A watchpoint is a mechanism provided by debuggers to halt program execution when the data contained by a particular memory address is changed. Watchpoints are inserted by the programmer to enable inspection of register contents, memory locations, and variable values when memory is written to test that the program is operating correctly. Watchpoints are removed after the program is successfully tested. <i>See also</i> Breakpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Way</b>                | <i>See</i> Cache way.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Word</b>               | A 32-bit data item.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Word-invariant</b>     | In a word-invariant system, the address of each byte of memory changes when switching between little-endian and big-endian operation, in such a way that the byte with address A in one endianness has address A EOR 3 in the other endianness. As a result, each aligned word of memory always consists of the same four bytes of memory in the same order, regardless of endianness. The change of endianness occurs because of the change to the byte addresses, not because the bytes are rearranged. The ARM architecture supports word-invariant systems in ARMv3 and later versions. When word-invariant support is selected, the behavior of load or store instructions that are given unaligned addresses is instruction-specific, and is in general not the expected behavior for an unaligned access. It is recommended that word-invariant systems should use the endianness that produces the desired byte addresses at all times, apart possibly from very early in their reset handlers before they have set up the endianness, and that this early part of the reset handler should use only aligned word memory accesses.<br><br><i>See also</i> Byte-invariant. |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Write</b>              | Writes are defined as operations that have the semantics of a store. That is, the ARM instructions SRS, STM, STRD, STC, STRT, STRH, STRB, STRBT, STREX, SWP, and SWPB, and the Thumb instructions STM, STR, STRH, STRB, and PUSH.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Write-back (WB)</b>    | In a write-back cache, data is only written to main memory when it is forced out of the cache on line replacement following a cache miss. Otherwise, writes by the processor only update the cache. (Also known as copyback).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Write buffer</b>       | A block of high-speed memory, arranged as a FIFO buffer, between the data cache and main memory, whose purpose is to optimize stores to main memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Write completion</b>   | The memory system indicates to the processor that a write has been completed at a point in the transaction where the memory system is able to guarantee that the effect of the write is visible to all processors in the system. This is not the case if the write is associated with a memory synchronization primitive, or is to a Device or Strongly Ordered region. In these cases the memory system might only indicate completion of the write when the access has affected the state of the target, unless it is impossible to distinguish between having the effect of the write visible and having the state of target updated. This stricter requirement for some types of memory ensures that any side-effects of the memory access can be guaranteed by the processor to have taken place. You can use this to prevent the starting of a subsequent operation in the program order until the side-effects are visible. |
| <b>Write-through (WT)</b> | In a write-through cache, data is written to main memory at the same time as the cache is updated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>WT</b>                 | <i>See</i> Write-through.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

### Cache terminology diagram

The diagram below illustrates the following cache terminology:

- block address
- cache line
- cache set
- cache way
- index
- tag.
